Abstract

The Panel on Plant Health performed a pest categorisation of the great spruce bark beetle, *Dendroctonus micans* (Kugelann), (Coleoptera: Curculionidae, Scolytinae), for the EU. *D. micans* is a well-defined and distinguishable species, recognised mainly as a pest of spruce (*Picea* spp.) and pine (*Pinus* spp.) in Eurasia. Attacks on other conifers (*Abies* spp., *Larix decidua*, *Pseudotsuga menziesii*) are also reported. Supposedly originating from north-eastern Eurasia, *D. micans* has spread westward and is now distributed throughout the EU (22 Member States). It is a quarantine pest listed in Annex IIB of Council Directive 2000/29/EC for Greece, Ireland and the United Kingdom (Northern Ireland, Isle of Man and Jersey) as protected zones. Wood, wood products, bark and wood packaging material of the conifers genera listed as hosts are considered as the main pathways for the pest, which is also able to disperse several kilometres by flight. The sib-mating habits of the species allow each single female to start a new colony on her own. The pest’s wide current geographic range suggests that it is able to establish anywhere in the EU where its hosts are present. The beetles attack living trees and usually complete their life cycle without killing their host, except under epidemic conditions at the limits of their distribution range, where hundreds of thousands of trees can be killed. Sitka spruce (*Picea sitchensis*) is particularly susceptible. Biological control using the very specific predatory beetle, *Rhizophagus grandis*, is a widespread and efficient option that has been implemented in all areas suffering from outbreaks. It is complemented by sanitary thinning or clear-felling. All criteria assessed by EFSA for consideration as potential protected zone quarantine pest were met. The criteria for considering *D. micans* as a potential regulated non-quarantine pest are not met since plants for planting are not the main pathway.

1. Introduction

1.1. Background and Terms of Reference as provided by the requestor

1.1.1. Background

Council Directive 2000/29/EC\(^1\) on protective measures against the introduction into the Community of organisms harmful to plants or plant products and against their spread within the Community establishes the present European Union plant health regime. The Directive lays down the phytosanitary provisions and the control checks to be carried out at the place of origin on plants and plant products destined for the Union or to be moved within the Union. In the Directive’s 2000/29/EC annexes, the list of harmful organisms (pests) whose introduction into or spread within the Union is prohibited, is detailed together with specific requirements for import or internal movement.

Following the evaluation of the plant health regime, the new basic plant health law, Regulation (EU) 2016/2031\(^2\) on protective measures against pests of plants, was adopted on 26 October 2016 and will apply from 14 December 2019 onwards, repealing Directive 2000/29/EC. In line with the principles of the above mentioned legislation and the follow-up work of the secondary legislation for the listing of EU regulated pests, EFSA is requested to provide pest categorizations of the harmful organisms included in the annexes of Directive 2000/29/EC, in the cases where recent pest risk assessment/pest categorisation is not available.

1.1.2. Terms of Reference

EFSA is requested, pursuant to Article 22(5.b) and Article 29(1) of Regulation (EC) No 178/2002\(^3\), to provide scientific opinion in the field of plant health.

EFSA is requested to prepare and deliver a pest categorisation (step 1 analysis) for each of the regulated pests included in the appendices of the annex to this mandate. The methodology and template of pest categorisation have already been developed in past mandates for the organisms listed in Annex II Part A Section II of Directive 2000/29/EC. The same methodology and outcome is expected for this work as well.

The list of the harmful organisms included in the annex to this mandate comprises 133 harmful organisms or groups. A pest categorisation is expected for these 133 pests or groups and the delivery of the work would be stepwise at regular intervals through the year as detailed below. First priority covers the harmful organisms included in Appendix 1, comprising pests from Annex II Part A Section I and Annex II Part B of Directive 2000/29/EC. The delivery of all pest categorisations for the pests included in Appendix 1 is June 2018. The second priority is the pests included in Appendix 2, comprising the group of Cicadellidae (non-EU) known to be vector of Pierce’s disease (caused by Xylella fastidiosa), the group of Tephritidae (non-EU), the group of potato viruses and virus-like organisms, the group of viruses and virus-like organisms of Cydonia Mill., Fragaria L., Malus Mill., Prunus L., Pyrus L., Ribes L., Rubus L. and Vitis L. and the group of Margarodes (non-EU species). The delivery of all pest categorisations for the pests included in Appendix 2 is end 2019. The pests included in Appendix 3 cover pests of Annex I part A section I and all pests categorisations should be delivered by end 2020.

For the above mentioned groups, each covering a large number of pests, the pest categorisation will be performed for the group and not the individual harmful organisms listed under ‘such as’ notation in the Annexes of the Directive 2000/29/EC. The criteria to be taken particularly under consideration for these cases, is the analysis of host pest combination, investigation of pathways, the damages occurring and the relevant impact.

Finally, as indicated in the text above, all references to ‘non-European’ should be avoided and replaced by ‘non-EU’ and refer to all territories with exception of the Union territories as defined in Article 1 point 3 of Regulation (EU) 2016/2031.

1.1.2.2. Terms of Reference: Appendix 2

List of harmful organisms for which pest categorisation is requested per group. The list below follows the categorisation included in the annexes of Directive 2000/29/EC.

Annex IAI

(a) Insects, mites and nematodes, at all stages of their development

Group of Cicadellidae (non-EU) known to be vector of Pierce’s disease (caused by *Xylella fastidiosa*), such as:

1) *Carneocephala fulgida* (Nottingham)
2) *Draculacephala minerva* Ball

Group of Tephritidae (non-EU) such as:

1) *Anastrepha fraterculus* (Wiedemann)
2) *Anastrepha ludens* (Loew)
3) *Anastrepha obliqua* Macquart
4) *Anastrepha suspensa* (Loew)
5) *Dacus ciliatus* Loew
6) *Dacus curcurbitae* Coquillett
7) *Dacus dorsalis* Hendel
8) *Dacus tryoni* (Froggatt)
9) *Dacus tsuneonis* Miyake
10) *Dacus zonatus* Saund.
11) *Epochra canadensis* (Loew)
12) *Pardalaspis cyanescens* Bezzi
13) *Pardalaspis quinaria* Bezzi
14) *Pterandrus rosa* (Karsch)
15) *Rhacochlaena japonica* Ito
16) *Rhagoletis completa* Cresson
17) *Rhagoletis fausta* (Osten-Sacken)
18) *Rhagoletis indifferens* Curran
19) *Rhagoletis mendax* Curran
20) *Rhagoletis pomonella* Walsh
21) *Rhagoletis suavis* (Loew)

(c) Viruses and virus-like organisms

Group of potato viruses and virus-like organisms such as:

1) Andean potato latent virus
2) Andean potato mottle virus
3) Arracacha virus B, oca strain
4) Potato black ringspot virus
5) Potato virus T
6) non-EU isolates of potato viruses A, M, S, V, X and Y (including Yo, Yn and Yc) and Potato leafroll virus

1) Blueberry leaf mottle virus
2) Cherry rasp leaf virus (American)
3) Peach mosaic virus (American)
4) Peach phony rickettsia
5) Peach rosette mosaic virus
6) Peach rosette mycoplasm
7) Peach X-disease mycoplasm
8) Peach yellows mycoplasm
9) Plum line pattern virus (American)
10) Raspberry leaf curl virus (American)
11) Strawberry witches’ broom mycoplasm

Annex IIAI

(a) Insects, mites and nematodes, at all stages of their development

Group of *Margarodes* (non-EU species) such as:

1) *Margarodes vitis* (Phillipi)
2) *Margarodes vredendalensis* de Klerk
3) *Margarodes prieskaensis* Jakubski
1.1.2.3. Terms of Reference: Appendix 3

List of harmful organisms for which pest categorisation is requested. The list below follows the annexes of Directive 2000/29/EC.

**Annex IAI**

(a) Insects, mites and nematodes, at all stages of their development

- Acleris spp. (non-EU)
- Amauromyza maculosa (Malloch)
- Anomala orientalis Waterhouse
- Arthenodes minutus Drury
- Choristoneura spp. (non-EU)
- Conotrachelus nenuphar (Herbst)
- Dendrolimus sibiricus Tschetverikov
- Diabrotica barberi Smith and Lawrence
- Diabrotica undecimpunctata howardi Barber
- Diabrotica undecimpunctata undecimpunctata Mannerheim
- Diabrotica virgifera zeae Krysan & Smith
- Diaphorina citri Kuway
- Heliothis zeae (Boddie)
- Hirschmanniella spp., other than Hirschmanniella gracilis (de Man) Luc and Goodey
- Liriomyza sativae Blanchard
- Meloidogyne fallax Karssen
- Popillia japonica Newman
- Longidorus diadecturus Eveleigh and Allen
- Monochamus spp. (non-EU)
- Myndus crudus Van Duzee
- Nacobbus aberrans (Thorne) Thorne and Allen
- Naupactus leucoloma Boheman
- Premnotrypes spp. (non-EU)
- Pseudopityophthorus minutissimus (Zimmermann)
- Pseudopityophthorus pruinosus (Eichhoff)
- Scaphoideus luteolus (Van Duzee)
- Spodoptera eridania (Cramer)
- Spodoptera frugiperda (Smith)
- Spodoptera litura (Fabricus)
- Thrips palmi Karny
- Xiphinema americanum Cobb sensu lato (non-EU populations)
- Xiphinema californicum Lamberti and Bleve-Zacheo

(b) Fungi

- Ceratocystis fagacearum (Bretz) Hunt
- Chrysomyxa arctostaphyli Dietel
- Cronartium spp. (non-EU)
- Endocronartium spp. (non-EU)
- Guignardia laricina (Saw.) Yamamoto and Ito
- Gymnosporangium spp. (non-EU)
- Inonotus weirii (Murril) Kotlaba and Pouzar
- Melampsora farlowii (Arthur) Davis
- Mycosphaerella larici-leptolepis Ito et al.
- Mycosphaerella populorum G. E. Thompson
- Phoma andina Turkensteen
- Phyllosticta solitaria Ell. and Ev.
- Septoria lycopersici Spec. var. malagutii Ciccarone and Boerema
- Thecaphora solani Barrus
- Trechispora brinkmannii (Bresad.) Rogers

(c) Viruses and virus-like organisms

- Tobacco ringspot virus
- Tomato ringspot virus
- Bean golden mosaic virus
- Cowpea mild mottle virus
- Lettuce infectious yellows virus
- Pepper mild tigré virus
- Squash leaf curl virus
- Euphorbia mosaic virus
- Florida tomato virus

(d) Parasitic plants

- Arceuthobium spp. (non-EU)

**Annex IAI I**

(a) Insects, mites and nematodes, at all stages of their development

- Meloidogyne fallax Karssen
- Popillia japonica Newman
- Rhizocus hibisci Kawai and Takagi
(b) Bacteria

Clavibacter michiganensis (Smith) Davis et al.  
Ralstonia solanacearum (Smith) Yabuuchi et al.  
ssp. sepedonicus (Spieckermann and Kotthoff)  
Davis et al.

(c) Fungi

Melampsora medusae Thümen  
Synchytrium endobioticum (Schilbersky) Percival

Annex I B

(a) Insects, mites and nematodes, at all stages of their development

Leptinotarsa decemlineata Say  
Liriomyza bryoniae (Kaltenbach)

(b) Viruses and virus-like organisms

Beet necrotic yellow vein virus

1.2. Interpretation of the Terms of Reference

Dendroctonus micans is one of a number of pests listed in the Appendices to the Terms of Reference (ToR) to be subject to pest categorisation to determine whether it fulfils the criteria of a quarantine pest or those of a regulated non-quarantine pest for the area of the EU excluding Ceuta, Melilla and the outermost regions of Member States referred to in Article 355(1) of the Treaty on the Functioning of the European Union (TFEU), other than Madeira and the Azores.

Since D. micans is regulated in the protected zones only, the scope of the categorisation is the territory of the protected zone (Greece, Ireland and the United Kingdom: Northern Ireland, Isle of Man and Jersey), thus the criteria refer to the protected zone instead of the EU territory.

2. Data and methodologies

2.1. Data

2.1.1. Literature search

A literature search on D. micans was conducted at the beginning of the categorisation in the ISI Web of Science bibliographic database, using the scientific name of the pest as search term. Relevant papers were reviewed, and further references and information were obtained from experts, from citations within the references and grey literature.

2.1.2. Database search

Pest information, on host(s) and distribution, was retrieved from the EPPO Global Database (EPPO, 2017).

Data about the area of hosts grown in the EU and about the import of commodity types that could provide a pathway for the pest to enter the EU from non-EU European countries were obtained from EUROSTAT.

The Europhyt database was consulted for pest-specific notifications on interceptions and outbreaks. Europhyt is a web-based network launched by the Directorate General for Health and Consumers (DG SANCO), and is a subproject of PHYSAN (Phyto-Sanitary Controls) specifically concerned with plant health information. The Europhyt database manages notifications of interceptions of plants or plant products that do not comply with EU legislation, as well as notifications of plant pests detected in the territory of the Member States (MSs) and the phytosanitary measures taken to eradicate or avoid their spread.

2.2. Methodologies

The Panel performed the pest categorisation for D. micans, following guiding principles and steps presented in the EFSA guidance on the harmonised framework for pest risk assessment (EFSA PLH Panel, 2010) and as defined in the International Standard for Phytosanitary Measures No 11 (FAO, 2013) and No 21 (FAO, 2004).
In accordance with the guidance on a harmonised framework for pest risk assessment in the EU (EFSA PLH Panel, 2010), this work was initiated following an evaluation of the EU’s plant health regime. Therefore, to facilitate the decision-making process, in the conclusions of the pest categorisation, the Panel addresses explicitly each criterion for a Union quarantine pest and for a Union regulated non-quarantine pest in accordance with Regulation (EU) 2016/2031 on protective measures against pests of plants, and includes additional information required as per the specific terms of reference received by the European Commission. In addition, for each conclusion, the Panel provides a short description of its associated uncertainty.

Table 1 presents the Regulation (EU) 2016/2031 pest categorisation criteria on which the Panel bases its conclusions. All relevant criteria have to be met for the pest to potentially qualify either as a quarantine pest or as a regulated non-quarantine pest. If one of the criteria is not met, the pest will not qualify. In such a case, the working group should consider the possibility to terminate the assessment early and to be concise in the sections preceding the question for which the negative answer is reached. Note that a pest that does not qualify as a quarantine pest may still qualify as a regulated non-quarantine pest which needs to be addressed in the opinion. For the pests regulated in the protected zones only, the scope of the categorisation is the territory of the protected zone, thus the criteria refer to the protected zone instead of the EU territory.

It should be noted that the Panel’s conclusions are formulated respecting its remit and particularly with regard to the principle of separation between risk assessment and risk management [EFSA founding regulation (EC) No 178/2002]; therefore, instead of determining whether the pest is likely to have an unacceptable impact, the Panel will present a summary of the observed pest impacts. Economic impacts are expressed in terms of yield and quality losses and not in monetary terms, while addressing social impacts is outside the remit of the Panel, in agreement with EFSA guidance on a harmonised framework for pest risk assessment (EFSA PLH Panel, 2010).

Table 1: Pest categorisation criteria under evaluation, as defined in Regulation (EU) 2016/2031 on protective measures against pests of plants (the number of the relevant sections of the pest categorisation is shown in brackets in the first column)

<table>
<thead>
<tr>

<tr>
<td>Absence/presence of the pest in the EU territory (Section 3.2)</td>
<td>Is the pest present in the EU territory? If present, is the pest widely distributed within the EU? Describe the pest distribution briefly!</td>
<td>Is the pest present in the EU territory? If not, it cannot be a protected zone quarantine organism.</td>
<td>Is the pest present in the EU territory? If not, it cannot be a regulated non-quarantine pest. (A regulated non-quarantine pest must be present in the risk assessment area).</td>
</tr>
<tr>
<td>Regulatory status (Section 3.3)</td>
<td>If the pest is present in the EU but not widely distributed in the risk assessment area, it should be under official control or expected to be under official control in the near future.</td>
<td>The protected zone system aligns with the pest free area system under the International Plant Protection Convention (IPPC). The pest satisfies the IPPC definition of a quarantine pest that is not present in the risk assessment area (i.e. protected zone).</td>
<td>Is the pest regulated as a quarantine pest? If currently regulated as a quarantine pest, are there grounds to consider its status could be revoked?</td>
</tr>
</tbody>
</table>
The Panel will not indicate in its conclusions of the pest categorisation whether to continue the risk assessment process, but, following the agreed two-step approach, will continue only if requested by the risk managers. However, during the categorisation process, experts may identify key elements and knowledge gaps that could contribute significant uncertainty to a future assessment of risk. It would be useful to identify and highlight such gaps so that potential future requests can specifically target the major elements of uncertainty, perhaps suggesting specific scenarios to examine.

3. **Pest categorisation**

3.1. **Identity and biology of the pest**

3.1.1. **Identity and taxonomy**

*D. micans* is an insect of the family Curculionidae, subfamily Scolytinae.  

3.1.2. **Biology of the pest**

*D. micans* colonises the phloem of living, apparently healthy conifers, mainly spruces and pines (Grégoire, 1988). As it is extremely resistant to the defensive monoterpenes of conifers (Everaerts et al., 1988), it does not need to mass attack and kill the trees in order to establish successfully. The sex ratio is biased (one male for 5–40 females; Francke-Grosmann, 1950) and the females are usually fertilised by a brother before they leave their natal tree (Vouland et al., 1984). The majority of the emerging insects are thus females that are immediately ready to start a new colony on their own. Each female solitarily attacks a new host, and creates a short 5–20 cm egg gallery on the side of which her eggs are laid in batches. Most of the time, there is only one or a few attacks per tree, and the tree survives. In many cases, the females have to try repeatedly to enter the trees, which resist by producing resin and eventually expelling the insects. In the field, an egg batch may include only a few or up to 200 eggs. The males also emerge and fly, and can occasionally visit a new egg gallery and fertilise a female that has already mated with a brother (Fraser et al., 2014). Quite unusually among bark beetles, the larvae feed in groups in the living phloem, pushing their frass behind them. After metamorphosis, the young adults spend several weeks to several months together, according to the season, and it is during this period that they mate. The life cycle can be completed in 1 year under mild climates (e.g. Brittany, France) or is protracted to one and a half or two years or even longer when the growing season is very short. Except for the monovoltine populations, the phenology of the species varies each year, and most of the developmental stages may be found throughout the year. When metamorphosis occurs in the summer or autumn, the young adults undergo an obligatory reproductive diapause and need to overwinter. When metamorphosis occurs in the spring, the adults can oviposit on the same year. Hosts are randomly selected but, once a tree has been successfully attacked, it is often re-attacked the following years (Gilbert et al., 2001). An important feature in *D. micans*’ biology is its association with an extremely specific predator, the Monotomid beetle *Rhizophagus grandis* Gyll. (Weber, 1900; Bergmiller, 1903; Grégoire, 1988). This insect is following *D. micans* in its geographical spread and, in many instances, has also been mass-produced and released for the biological control of *D. micans* (Kobakhidze et al., 1968; Evans et al., 1984; Grégoire et al., 1984; Yüksel, 1996).

3.1.3. **Intraspecific diversity**

Intraspecific diversity appears extremely low over most of the geographical range. Mayer et al. (2015) sequenced three polymorphic molecular markers in samples from 110 localities in Europe, Siberia, Caucasus and the Russian Far East, and found very little differences between the local populations in Europe, Siberia and the Caucasus (1–4 mutation between different locations for the mitochondrial marker COI, none for two nuclear markers). The populations from the Russian Far East
showed a slightly higher distance from the former group (one mutation for the two nuclear markers, 9-14 mutational steps for the COI sequences).

### 3.1.4. Detection and identification of the pest

**Are detection and identification methods available for the pest?**

**Yes**, the organism can be detected by visual searching, often after damage symptoms are seen. The species can be identified by examining morphological features, for which keys exist, e.g. Balachowsky (1949); Grüne (1979); Schedl (1981); Wood (1982).

Because there are only one or a few attacks per tree and the attacked trees generally do not die under endemic conditions, symptoms must be searched very carefully. When expelling their frass and the resin secreted by the tree from their egg gallery, the females build a tube around the entry hole with this material. The colour of this ‘resin tube’ ranges from amber to purple or dark brown, turning greyish with time. The proportion of frass in the tube is an indicator of the female’s success (the more resin and less frass, the less successful the egg gallery). In addition, resin pellets (whitish to purplish) are also expelled from the galleries, and liquid resin can also flow on the surface of the bark. There are often more resin tubes than actual successful brood systems, because of many abortive attempts. The attacks often occur at the base of the trees, or even on the roots, below the surface. They are then often betrayed by resin pellets at the surface of the litter. Woodpecker damage (holes in the bark, bark flakes detached) is also a symptom of attack. Under epidemic conditions, there are more attacks per tree and, depending on the tree species, there can be significant mortality in the stands.

On a wider scale, when trees are killed, the insects can be detected by helicopter surveys followed by ground inspections of any dead trees, as done in Scotland (Nick Fielding, Forest Research UK, personal communication, 6 March 2017, see Appendix A).

The adults are the largest bark beetles in Eurasia. They are black and measure ca 8 mm in length. The larvae feed side by side; the pupae are distributed among the frass in the brood chambers.

### 3.2. Pest distribution

#### 3.2.1. Pest distribution outside the EU

*D. micans* is present in two continents, Europe and Asia, and is thought to have originated in Eastern Siberia or in the Russian Far East (Mayer et al., 2015). In non-EU Europe, the insect has been reported from Bosnia and Herzegovina, Georgia, Norway, Russia, Serbia, Switzerland, Turkey and Ukraine (Figure 1).
3.2.2. Pest distribution in the EU

As the insect is very inconspicuous at the endemic stage, it is probably more widespread in the areas where it is known as established than usually reported. However, its presence in Protected Zones would be obvious as, before biological control is established in a newly colonised area, destructive outbreaks usually occur (see Section 3.5.2.1).

3.3.3. Legislation addressing the organisms vectored by *Dendroctonus micans* (Directive 2000/29/EC)

No specific legislation is known. For further information on the organisms vectored by *D. micans*, see Section 3.5.2.2.

3.4. Entry, establishment and spread in the EU

3.4.1. Host range

*D. micans* attacks various indigenous or introduced conifers. Spruce is the main host, in particular *Picea abies*, *Picea obovata*, *Picea orientalis* and *Picea sitchensis*, but other *Picea* species can also be attacked, such as *Picea ajanensis*, *Picea breweriana*, *Picea engelmannii*, *Picea glauca*, *Picea jezoensis*, *Picea mariana*, *Picea obovata*, *Picea omorika*, *Picea pungens*. *Pinus sylvestris* is regularly attacked in...
the Baltic area and in Siberia. Other pines (Pinus contorta, Pinus nigra var. austriaca, Pinus sibirskyi, Pinus strobus, Pinus uncinata) have also been observed to be sporadically attacked, as well as firs (Abies alba, Abies holophylla, Abies nordmanniana, Abies pectinata, Abies sibirica), larch (Larix decidua) and Douglas-fir (Pseudotsuga menziesii) (Grégoire, 1988; Mayer et al., 2015).

The hosts for which D. micans is regulated are comprehensive of the host range: the pest is regulated on five genera: Abies, Larix, Picea, Pinus and Pseudotsuga.

3.4.2.  Entry

Is the pest able to enter into the protected zone areas of the EU territory? If yes, identify and list the pathways!

Yes, the pest is already established in 22 MSs. Since entry by natural dispersal from EU areas where the pest is present is possible, only isolated areas (e.g. islands) can be protected zones. So, Greece is very likely to be invaded sooner or later by natural dispersal.

The pest was first recorded in Europe by the end of the 18th century (Grégoire, 1988).

The main pathways are:

- wood of Abies, Larix, Pinus, Picea and Pseudotsuga from countries where the pest occurs;
- wood chips of conifers from countries where the pest occurs;
- bark of conifers from countries where the pest occurs;
- wood packaging material and dunnage from countries where the pest occurs.

Plants for planting of Abies, Larix, Pinus, Picea and Pseudotsuga from countries where the pest occurs are regarded as a very minor pathway for these bark beetles, because it is very unlikely that they will attack young trees in a tree nursery. The smallest attacked trees under intense outbreak conditions had a diameter at breast height of 7 cm (Grégoire, 1988).

As shown in Table 2, D. micans is present in most of the EU, except in Ireland, Greece, Portugal, and Spain, while there is no information from Cyprus and Malta in the EPPO Global Database (EPPO, 2017). An important potential pathway is the trade in infested logs (Kobakhidze, 1967; Bevan and King, 1983; Pauly and Meurisse, 2007), but specific requirements are in place for the trade in wood to protected zones (see Section 3.3.2). According to the EUROSTAT database, there are movements of material pertaining to the above pathways from Third countries and EU countries where the pest is present, into the protected zones. For example, concerning the wood pathway, around 49,000 tonnes of coniferous wood including the genera Picea, Pinus and Abies (Eurostat codes 44032011, 44032019, 44022031, 44032039, 44022091, 44032099) has been imported in the period 2011-2015 from EU countries into protected zones. In the same period, around 9,000 tonnes of coniferous wood were imported into the protected zones from third countries where the pest is present (Bosnia and Herzegovina, Norway, Russia, Serbia, Switzerland, Turkey and Ukraine). It should be noted that these data are overestimated because data for the whole UK were used, whereas only Northern Ireland, the Isle of Man and Jersey are protected zones.

Entry into protected zones, such as Greece, can occur by natural dispersal from adjacent infested areas. The pest is widespread in Bulgaria (Table 2) and there is a continuity of spruce coverage between this latter country and Greece (Figure 2). The beetles are able to fly 10 km or more in laboratory flightmills (Forssé, 1989; Gilbert et al., 2003). It has also to be remembered that one single female, usually fertilised by a brother, is able to found a new colony (Grégoire, 1988).

3.4.3.  Establishment

Is the pest able to become established in the protected zone areas of the EU territory?

Yes, the pest is already established in 22 MSs. The climate of the EU Protected Zones is similar to that of the MSs where D. micans is established, and the pest’s main host plants are present (Figures 2-4)
3.4.3.1. EU distribution of main host plants

The wide distribution of host trees in the EU territory allowed \textit{D. micans} to establish in most MSs (see Table 2). Norway spruce (\textit{Picea excelsa}) and Scots pine (\textit{Pinus sylvestris}) are native to Europe (Figure 2), and are widely planted outside their original range throughout the EU. The very susceptible Sitka spruce (\textit{Picea sitchensis}, from Western North America) is also very commonly planted, particularly in Ireland and the UK which are protected zones (Figure 2B). Many other hosts are widely distributed in the EU territory (Figure 2A,C).

\begin{figure}[h]
\centering

\caption{Relative probability of presence of species/genera from the European Atlas of Forest Tree Species and the related trustability of RPP}
\end{figure}

\textbf{Figure 2:} Relative probability of presence of species/genera from the European Atlas of Forest Tree Species and the related trustability of RPP
3.4.3.2. Climatic conditions affecting establishment

Given the current distribution of *D. micans*, the whole EU area (including protected zones) is suitable for establishment.

3.4.4. Spread

*Figure 2: continued*

**3.4.3.2. Climatic conditions affecting establishment**

Given the current distribution of *D. micans*, the whole EU area (including protected zones) is suitable for establishment.

**3.4.4. Spread**

Is the pest able to spread within protected zones areas of the EU territory following establishment? How?

**Yes**, adults can disperse naturally. They can fly 10 km or even more. The pest can also spread by human assistance, e.g. with the transportation of wood, wood chips, bark, wood packaging material and dunnage of conifers from infested areas.

Regulated non-quarantine pests: Is spread mainly via specific plants for planting, rather than via natural spread or via movement of plant products or other objects?

**No**, plants for planting are not the main pathway for bark beetles, because natural spread and the transport of infested wood is the main pathway and it is unlikely, although not completely impossible, that beetles will attack young trees in a tree nursery (see Section 3.4.2).
As shown in Table 2, *D. micans* is present in most of the EU, except in Ireland, Greece, Portugal and Spain, while there is no information from Cyprus and Malta in the EPPO Global Database. The main pathway for spread is the transportation of infested logs (Kobakhidze, 1967; Bevan and King, 1983; Pauly and Meurisse, 2007). Autonomous dispersal by flight is also possible, the beetles being able to fly 10 km or more in laboratory flightmills (Forsse, 1989; Gilbert et al., 2003). It has to be remembered that one single female, usually fertilised by a brother, is able to found a new colony (Grégoire, 1988).

Therefore, natural spread from infested areas to protected zones as for example Greece can occur, because the pest is present in neighbouring countries such as Bulgaria and Turkey.

### 3.5. Potential or observed impacts in the EU

**Would the pests’ introduction have an economic or environmental impact on the protected zones of the EU?**

**Yes**, the pest is known to kill trees, sometimes in high numbers. In newly colonised areas, it could cause economic and environmental impact during a few years after its entry.

Outbreaks usually occur when the pest reaches new territories. Important tree mortality can be observed, particularly in the more susceptible Sitka spruce. Once the specific predator *Rhizopagus grandis* is established, either naturally or through inoculative releases, damage subside within 6–8 years. During and after particularly dry years, small, limited outbreaks can occur in spite of the presence of the natural enemies.

#### 3.5.1. Potential pest impacts

**3.5.1.1. Direct impacts of the pest**

Outbreaks of *D. micans* have been reported from Siberia (Kolomiets and Bogdanova, 1976), as well as from the Baltic areas of Russia and from Belarus (Krivosheina and Aksentev, 1984). The pest invaded Georgia in 1956, probably travelling with timber imported from Russia, and attacked tens of thousands hectares of *Picea orientalis* (Kobakhidze, 1967). It then invaded Turkey, leading to the clearfelling of ca 7 million m³ over 120,000 ha (Akinci et al., 2009). Because *D. micans* does not vector pathogenic fungi (see Section 3.5.2.2), the quality of the attacked timber is not affected.

#### 3.5.1.2. Indirect pest impacts (e.g. by bacteria or viruses transmitted by the pest)

Some fungi can be occasionally vectored by *D. micans* (see Section 3.5.2.2).

#### 3.5.2. Observed pest impacts in the EU

**3.5.2.1. Direct impact of the pest**

Under outbreak conditions at the limits of the extension range where biological control is not yet established, attacked trees can die, especially *Picea sitchensis*, sometimes in large numbers. In the French Massif Central, several thousand hectares of *Picea excelsa* were affected in the years 1970–1980 (Vouland and Schvester, 1994); in Great-Britain, surveys in 1982–1984 revealed that tens of thousands of trees have been attacked during this period (Fielding and Evans, 1997). However, contrary to damage exerted by mass-attacking, tree-killing bark beetles such as *Ips typographus*, the trees attacked by *D. micans* do not show any discoloration lowering the value of the wood.

**3.5.2.2. Indirect pest impact (e.g. by bacteria or viruses transmitted by the pest)**

Very little fungi are reported to be associated to *D. micans*. Lieutier et al. (1992) found *Ophiostoma canum* in variable proportions (32–92% of 155 flying beetles; 0.5–90% of 140 induced attacks), and only one observation of *Ophiostoma pennisulcatum* and seven observation of *Ophiostoma* sp. From artificial inoculations on *Pinus sylvestris*, Solheim et al. (2001) concluded that *O. canum* had a low virulence, inducing lesions similar to those provoked by sterile control inoculations. Under endemic conditions, the trees survive the attacks and bear no symptoms of fungal activity (blue staining) (Grégoire, 1988).
3.6. Availability and limits of mitigation measures

Are there feasible and effective measures available to prevent the entry into, establishment within, or spread of the pest within the protected zone areas of the EU such that the risk becomes mitigated?

Yes, in isolated areas (e.g. islands) that cannot be reached by natural spread, measures can be put in place to prevent the introduction with wood and bark. Debarking wood and heat treatment of wood, bark and chips is effective as specified in annex IVB of 2000/29/EC.

There are no effective measures to prevent establishment and spread.

Is it possible to eradicate the pest in a restricted area within 24 months after the presence of the pest was confirmed in the PZ?

No, the pest is very cryptic during the first years after its entry and establishment. The attacks are inconspicuous, and the attacked trees do not die before a sufficient number of broods have been established. Therefore, when the first symptoms appear, the established populations are already large and widespread.

However, there are no effective measures to prevent natural spread, because the removal of all host plants surrounding an area where the pest occurs is not feasible, and controlling the movements of infested material appears limited. After the entry of *D. micans* in Britain (Bevan and King, 1983), despite thorough control measures (surveys, sanitation, proscription of the movement of material from infested areas), *D. micans* has been able to spread into new areas in most of the country, except the North of Scotland (O’Neill and Evans, 1999; Gilbert et al., 2003; Appendix A).

3.6.1. Biological or technical factors affecting the feasibility and effectiveness of measures to prevent the entry, establishment and spread of the pest

- *D. micans* is a cryptic species, with solitary, fertilised females colonising alone healthy trees. The attacked trees often only show very little external symptoms;
- Because one single female is able to found a colony, and because sib-mating in the brood is the rule, the Allee threshold for *D. micans* is very low;
- *D. micans* attacks living trees, which greatly increases its range of suitable hosts as compared to species less resistant to conifer defences, and which need to find weakened hosts.

3.6.2. Control methods

- Sanitary thinning and clearfelling. However, these measures are not sufficient without biological control.
- Biological control using *Rhizophagus grandis*. This practice is already implemented in all areas presently affected by *D. micans*. (currently Georgia, Turkey, Great Britain and France; see Section 3.1.2).
- Attempts at eradication have been unsuccessful so far (see Section 3.6).

3.7. Uncertainty

*D. micans* has been exhaustively studied since it entered Europe. Its biology, ecology, relationships to its hosts and to natural enemies are well understood. There is some uncertainty regarding the possibility that the pest could occasionally use plants for planting as a pathway.
4. Conclusions

*D. micans* meets the criteria assessed by EFSA for consideration as a potential protected zone quarantine pest for the territory of the protected zones: Greece, Ireland and the United Kingdom (Northern Ireland, Isle of Man and Jersey) (Table 5).

Table 5: The Panel’s conclusions on the pest categorisation criteria defined in Regulation (EU) 2016/2031 on protective measures against pests of plants (the number of the relevant sections of the pest categorisation is shown in brackets in the first column)

Appendix A – Personal communication

Personal communication by Nick Fielding, Forest Research UK, 6 March 2017:

*Dendroctonus micans* is now found everywhere in Wales, more or less everywhere in England (more commonly in the west of the country reflecting where spruce is mainly grown); but is now getting a foothold in Scotland. The attached map shows the current distribution. I continue to rear *Rhizophagus grandid* and to treat any new finds of *D. micans*, but the rearing is on a much reduced scale. Most spruce woodland in Scotland is flown by helicopter and inspected from the air so the distribution is very accurate; this is followed by ground inspections of any dead or dying trees.
