This article can be cited before page numbers have been issued, to do this please use: P. A. Petrov, D. Yu. Naumov, T. S. Sukhikh, S. N. Konchenko, C. J. Gomez Garcia and R. Llusar, New J. Chem., 2017, DOI: 10.1039/C7NJ01217A.

This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the author guidelines.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard Terms \& Conditions and the ethical guidelines, outlined in our author and reviewer resource centre, still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.

# Synthesis, molecular structures and EPR spectra of the paramagnetic cuboidal clusters with $\mathrm{Mo}_{3} \mathrm{~S}_{4} \mathrm{Ga}$ core ${ }^{\dagger}$ 

Pavel A. Petrov, ${ }^{\text {ab }}$ Dmitry Yu. Naumov, ${ }^{\text {a }}$ Taisiya S. Sukhikh, ${ }^{\text {ab }}$ Sergey N. Konchenko, ${ }^{\text {ab }}$ Carlos J. Gómez-García, ${ }^{\text {c }}$ and Rosa Llusar* ${ }^{\text {d }}$

Electron precise $\left[\mathrm{Mo}_{3}\left(\mu_{3}-\mathrm{S}\right)(\mu-\mathrm{S})_{3}(\text { diphos })_{3} \mathrm{Br} 3\right] \mathrm{Br}$ (diphos $=\mathrm{dppe}$, dmpe) incomplete cuboidal clusters with six cluster skeletal electrons (CSE) were converted into paramagnetic cuboidal $\left[\mathrm{Mo}_{3}(\mathrm{GaBr})\left(\mu_{3}-\mathrm{S}\right)_{4}(\text { diphos })_{3} \mathrm{Br}_{3}\right]$ clusters by treatment with elemental Ga . The new heterobimetallic complexes with nine CSE possess a doublet ground state with the unpaired electron density delocalized over the three molybdenum atoms.

The cubane-type $\mathrm{M}_{4} \mathrm{~S}_{4}$ unit is known for many metals including molybdenum and gallium. ${ }^{1}$ Heterobimetallic $\mathrm{Mo}_{3} \mathrm{M}^{\prime} \mathrm{S}_{4}$ cores are also known for both transition and post-transition metals and they are synthesized by incorporating the $\mathrm{M}^{\prime}$ metal into a preformed $\mathrm{Mo}_{3}\left(\mu_{3}-S\right)(\mu-S)_{3}$ fragment, represented in Scheme 1. The most common sources of this $\mathrm{Mo}_{3} \mathrm{~S}_{4}$ fragment are the $\left[\mathrm{Mo}_{3} \mathrm{~S}_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{9}\right]^{4+}$ aqua ion, the $\left.\mathrm{Mo}_{3} \mathrm{~S}_{4}\left(\eta^{5}-\mathrm{Cp}^{\#}\right)_{3}\right]^{+}\left(\mathrm{Cp}^{\#}=\mathrm{C}_{5} \mathrm{H}_{5}\right.$, $\mathrm{C}_{5} \mathrm{H}_{4} \mathrm{Me}$, or $\mathrm{C}_{5} \mathrm{Me}_{5}$ ) cations and the $\left.\left[\mathrm{Mo}_{3} \mathrm{~S}_{4} \text { (diphosphane) }\right)_{3} \mathrm{X}_{3}\right]^{+}$ ( $\mathrm{X}=$ halogen) complexes. ${ }^{2}$ However, up to date post-transition groups $13-15$ metals have only been incorporated into the $\left[\mathrm{Mo}_{3} \mathrm{~S}_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{9}\right]^{4+}$ ion to afford single cubanes as well as cornershared double cubane structures (see Scheme 1, metal-metal bonds are omitted for clarity). ${ }^{3}$ Interconversion between single and double cubane structures is initiated by a redox change. In the case of gallium, only single cubane structures have been characterized to date. The $\left[\mathrm{Mo}_{3} \mathrm{GaS}_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{12}\right]^{5+}$ and $\left[\mathrm{Mo}_{3} \mathrm{GaS}_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{12}\right]^{6+}$ complexes have been prepared by reacting the $\left[\mathrm{Mo}_{3} \mathrm{~S}_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{9}\right]^{4+}$ aqua ion with gallium metal in 0.5 and 2 M $\mathrm{HCl}(\mathrm{aq})$, respectively. ${ }^{4 a}$ Reaction of the $\mathrm{Mo}_{3} \mathrm{~S}_{4}{ }^{4+}$ aqua ion with $\mathrm{Ga}^{3+}$ in the presence of $\mathrm{NaBH}_{4}$ as reducing agent exclusively affords the $\left[\mathrm{Mo}_{3} \mathrm{GaS}_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{12}\right]^{5+}$ cluster cation. ${ }^{4 b}$

[^0]Our groups have extensively investigated the chemistry of diphosphane-substituted $\mathrm{Mo}_{3} \mathrm{~S}_{4}$ complexes and we have isolated a series of heterobimetallic single cubane $\mathrm{Mo}_{3} \mathrm{M}^{\prime} \mathrm{S}_{4}$ derivatives for $\mathrm{M}^{\prime}=\mathrm{Fe}^{5}, \mathrm{Co}^{6}, \mathrm{Ni}^{7}$ and $\mathrm{Cu}^{8}$. In an attempt to extend this chemistry to post-transition metals, we reacted the cationic $\left[\mathrm{Mo}_{3} \mathrm{~S}_{4}(\mathrm{dppe})_{3} \mathrm{Br}_{3}\right]^{+}$cluster (dppe $=1,2-$ bis(diphenylphosphinoethane) with an excess of gallium metal resulting in the one-electron reduction of the cluster core, to afford unusual paramagnetic $\left[\mathrm{Mo}_{3} \mathrm{~S}_{4}(\mathrm{dppe})_{3} \mathrm{Br}_{3}\right]$ complex. ${ }^{9}$ In a similar way, its tungsten congener $\left[\mathrm{W}_{3} \mathrm{~S}_{4}(\mathrm{dppe})_{3} \mathrm{Br}_{3}\right]$ has also been isolated. ${ }^{10}$ These $\left[\mathrm{M}_{3} \mathrm{~S}_{4}(\mathrm{dppe})_{3} \mathrm{Br}_{3}\right.$ ] paramagnetic clusters with seven cluster skeletal electrons (CSE) constitute rare examples of $\mathrm{Mo}_{3} \mathrm{Q}_{4}$ complexes, which are, in general, electron precise with 6 CSE for the formation of three metal-metal bonds. It is noteworthy that the reaction of the analogous $\left[\mathrm{Mo}_{3} \mathrm{Se}_{4}(\mathrm{dppe})_{3} \mathrm{Br}_{3}\right]^{+}$cluster selenide with gallium results in a core transformation to afford a bicapped $\mathrm{Mo}_{3} \mathrm{Se}_{5}$ cluster complex. ${ }^{11}$ These results evidence the unique reactivity of gallium and prompted us to further study its incorporation into the $\mathrm{Mo}_{3} \mathrm{~S}_{4}$ core in order to obtain diphosphane $\mathrm{Mo}_{3} \mathrm{GaS}_{4}$ derivatives.

NJC

## COMMUNICATION

Scheme 1

As highlighted in the introduction, metallic gallium can serve as one-electron reductant transforming the 6 CSE electron precise $\mathrm{Mo}_{3} \mathrm{~S}_{4}$ diphosphane cluster cation to its neutral 7 CSE congener. When the reaction between [ $\mathrm{Mo}_{3} \mathrm{~S}_{4}$ (diphosphane) $\left.)_{3} \mathrm{Br}_{3}\right] \mathrm{Br}$ and gallium is carried out under rigorous air-free conditions for two weeks reaction time, as represented in Scheme 2, cubane type clusters $\left[\mathrm{Mo}_{3} \mathrm{GaS}_{4}(\mathrm{dppe})_{3} \mathrm{Br}_{4}\right]$ (1) and $\left[\mathrm{Mo}_{3} \mathrm{GaS}_{4}(\mathrm{dmpe})_{3} \mathrm{Br}_{4}\right]$ (2) are

${ }^{a}$ Standard deviations are given in parentheses; standard deviations for averaged values are given in square brackets. ${ }^{b} \mu_{3}-S$ capping $\mathrm{Mo}_{3}$ face. ${ }^{c} \mu_{3}-S$ capping $\mathrm{Mo}_{2} \mathrm{Ga}$ face. ${ }^{d}$ Distance trans to the $\mathrm{Mo}-\mathrm{P}$ bond. ${ }^{e}$ Distance trans to the $\mathrm{Mo}-\mathrm{Br}$ bond.

The crystal structures of 1•4.5THF and 2-THF were determined by single crystal X-ray diffraction, and both complexes share identical structural features. $\ddagger$ An ORTEP drawing of the
formed, and can be isolated in moderate yields (see Scheme 2). It is reasonable to assume that the reduced $\mathrm{Mo}_{3} \mathrm{~S}_{4}$ (diphosphane) $3_{3} \mathrm{Br}_{3}$ species with 7 CSE are formed first along with low valent gallium halides, resulting from the oxidation of gallium metal. Then, formal addition of a $\mathrm{Ga}^{\prime} \mathrm{Br}$ vertex to the trimetallic 7 CSE cluster produces 1 and 2, both containing 9 CSE . The two other $\mathrm{Mo}_{3} \mathrm{Ga}$ clusters reported to date $\left[\mathrm{Mo}_{3} \mathrm{GaS}_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{12}\right]^{5+}$ and $\left[\mathrm{Mo}_{3} \mathrm{GaS}_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{12}\right]^{6+}$ contain 8 and 7 CSE, respectively. Incidentally, reaction of $\left[\mathrm{Mo}_{3} \mathrm{~S}_{4}(\text { dppe })_{3} \mathrm{Cl}_{3}\right] \mathrm{Cl}$ or $\left[\mathrm{W}_{3} \mathrm{~S}_{4}(\text { dppe })_{3} \mathrm{Br}_{3}\right] \mathrm{Br}$ with an excess of gallium metal always stops at the reduction stage and without evidence for $\mathrm{Mo}_{3} \mathrm{GaS}_{4}$ or $\mathrm{W}_{3} \mathrm{GaS}_{4}$ species. Moreover, we were unable to isolate the reduced $7 \mathrm{CSE} \quad \mathrm{Mo}_{3} \mathrm{~S}_{4}(\mathrm{dmpe})_{3} \mathrm{Br}_{3}$ derivative with a less bulkier and more basic diphosphane than dppe, and reaction of $\left[\mathrm{Mo}_{3} \mathrm{~S}_{4}(\mathrm{dmpe})_{3} \mathrm{Br}_{3}\right] \mathrm{Br}$ with gallium always yielded invariably to $\mathbf{2}$ as the only isolable product.
molecular structure of $\mathbf{2}$ is represented in Figure 1. Both structures consist of discrete molecules of 1 and 2 with a central $\mathrm{Mo}_{3} \mathrm{Ga}$ core. Compound 2 crystallizes in trigonal $R 3 c$
space group with the $\mathrm{S} 4, \mathrm{Br} 4$ and Ga 1 atoms lying on a $C_{3}$ axis with a unique $\mathrm{Mo}-\mathrm{Mo}$ bond distance of 2.7784(6) $\AA$ And a $54-$ $\mathrm{Ga} 1-\mathrm{Br} 4$ angle of $180^{\circ}$. The $\mathrm{Mo}_{3}$ triangle in 1 shows small deviations from a three-fold symmetry (ESI, Fig. S1). The MoMo bond lengths in 1 fall within the range 2.7756(7)2.8132(7) $\AA$ and the Br atom coordinated to Ga is deviated from the central $\mathrm{S} 4-\mathrm{Ga} 1$ axis ( $\angle \mathrm{S} 4-\mathrm{Ga} 1-\mathrm{Br} 4$ equals $\left.175.52(5)^{\circ}\right)$. Table 1 lists the most relevant bond distances of compounds 1 and 2 together with those reported for the closely related $\mathrm{Mo}_{3} \mathrm{GaS}_{4}$ aqua clusters.

Fig. 1 ORTEP drawing of 2 with 50 \% thermal ellipsoids and atom-numbering scheme. Hydrogen atoms are omitted for clarity.

The average Mo-Mo bond distance in 1 of $2.795[18] \AA$ is slightly shorter, by $0.03 \AA$, than that observed for its parent cluster $\left[\mathrm{Mo}_{3} \mathrm{~S}_{4}(\mathrm{dppe})_{3} \mathrm{Br}_{3}\right]$ with $7 \operatorname{CSE} \quad\left(2.82[3] \AA\right.$ A). ${ }^{9}$ The shortening of the Mo-Mo or W-W bond is typical when a post-transition element is added to the $M_{3} S_{4}$ unit to form a heterocubane $\mathrm{M}_{3} \mathrm{M}^{\prime} \mathrm{S}_{4}$ core. The opposite tendency is found for the $\mathrm{Mo}-\mathrm{Mo}$ bond distances in $\left[\mathrm{Mo}_{3} \mathrm{GaS}_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{12}\right]^{5+}$ (2.735[8] $\AA$ ) and $\left[\mathrm{Mo}_{3} \mathrm{~S}_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{9}\right]^{4+}$ (2.713[3] $\AA$ ). There is an increase in the $\mathrm{Mo}-\mathrm{Mo}$ bond lengths on going from $\left[\mathrm{Mo}_{3} \mathrm{GaS}_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{12}\right]^{6+}$ with 7 CSE to $\left[\mathrm{Mo}_{3} \mathrm{GaS}_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{12}\right]^{5+}$ with 8 CSE and to $\mathbf{1}$ and $\mathbf{2}$ with 9 CSE. This increase in Mo-Mo bond lengths in accompanied by a significant decrease of $c a .0 .2-0.3$ $\AA$ Å in the Mo-Ga bond distances. The coordination environment of molybdenum in $\mathbf{1}$ and $\mathbf{2}$ is similar to that of their trimetallic $\left[\mathrm{Mo}_{3} \mathrm{~S}_{4} \text { (diphosphane) }\right)_{3} \mathrm{X}_{3}$ ] precursors. The gallium atom in $\mathbf{1}$ and 2 has tetrahedral coordination in contrast with the octahedral environment found for the $\mathrm{Mo}_{3} \mathrm{GaS}_{4}$ aqua clusters. Compounds $\mathbf{1}$ and $\mathbf{2}$ with an odd number of electrons are expected to be paramagnetic. At 300 K the product of the molar magnetic susceptibility times the temperature, $\chi_{m} \mathrm{~T}$, for $\mathbf{1}$ (see Figure S2) and $\mathbf{2}$ equals $c a .0 .34$ emu $\mathrm{K} \mathrm{mol}^{-1}$ in both compounds (near the expected value of 0.375 for one unpaired electron) and remains almost constant when the temperature is decreased, as expected for a paramagnetic system. The isothermal magnetization at 2 K (Figure S3) shows a saturation values close to $1 \mu_{\mathrm{B}}$, confirming the presence of
single unpaired electron in both compounds. The Q-band solid state EPR spectra of solid samples of $\mathbf{1}$ and $\mathbf{2}$ are very similar (Figures 2 and S4, respectively) with only one signal whose intensity increases upon decreasing the temperature. The signal presents axial anisotropy in both compounds although in compound $\mathbf{2}$ it shows a rhombic anisotropy at very low temperatures. This fact may be due to the larger distortions in the Mo coordination environment in 2. Thus, $\mathbf{2}$ has a more rhombic coordination environment with three different Mo-S bond distances (2.3624(13), 2.3904(11) and 2.4296(11) Å, Table 1) whereas in 1 we observe a more axial distortion since two of these distances are almost identical (ca. 2.354, 2.391 and 2.399 Å). Both compounds show no hyperfine splitting at low temperature indicating that the unpaired electron is delocalized over the three metal centres. In contrast, the unpaired electron density in the trinuclear cluster $\left[\mathrm{Mo}_{3} \mathrm{~S}_{4}(\mathrm{dppe})_{3} \mathrm{Br}_{3}\right]$ is localized on one metal centre. ${ }^{9}$ The electronic structures calculated for $\left[\mathrm{Mo}_{3} \mathrm{GaS}_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{12}\right]^{5+/ 6+}$ using the spin polarized discrete variational DV-X $\alpha$ method shows that the orbitals in the HOMO-LUMO region consist mainly of Mo 4d atomic orbitals. These results are in agreement with the absence of hyperfine splitting at low temperatures in the registered EPR spectra. ${ }^{4}$

Fig. 2 Q-band solid state EPR spectrum of 1 at different temperatures.
In conclusion, interaction of the trimetallic $\mathrm{Mo}_{3} \mathrm{~S}_{4}$ clusters with gallium causes transformation of the cluster core to afford the first examples of a $\mathrm{Mo}_{3} \mathrm{Ga}\left(\mu_{3}-\mathrm{S}\right)_{4}$ cluster core coordinated by diphosphane ligands. The cubane-like core formation likely goes through the step of one electron reduction of the $\mathrm{Mo}_{3} \mathrm{~S}_{4}$ unit. The two isolated heterobimetallic cluster complexes possess an odd number of electrons resulting in a $S=1 / 2$ ground state. The latter was evidenced by means of magnetic susceptibility measurements and confirmed by EPR spectroscopy.
