#### Abstract

The diastereoselectivity of the nucleophilic epoxidation of 3-hydroxy-2-methylene esters has been studied. The 3-hydroxy-2-methylene esters were obtained through a Morita-Baylis-Hillman reaction. The resulting epoxyesters were treated with thiophenol for transformation into 2,3-dihydroxy-2-((phenylthio)methyl) which upon treatment with triphosgene afforded the corresponding cyclic carbonates.

## Introduction

Stereoselective synthesis of $\alpha, \beta$-epoxyesters is of considerable synthetic interest because a number of compounds can be obtained by the opening of the oxirane ring. ${ }^{1-9}$ A convenient method for the preparation of $\alpha, \beta-$ epoxyesters is via nucleophilic epoxidation of chiral $\alpha, \beta$-unsaturated esters. ${ }^{2}$ We previously reported that the nucleophilic epoxidation of $\gamma$-hydroxy- $\alpha, \beta$-unsaturated esters ${ }^{8}$ (Scheme 1) is a diastereoselective reaction that favor

[^0]the syn isomer. We have also reported that the stereoselectivity depends highly on the substitution of the double bond and that high syn stereoselectivity ( $\mathrm{dr}>19: 1$ ) is observed for the $\alpha$-methyl-substituted enoates ${ }^{9}$ (Scheme 1 ). Free hydroxyl group resulted to be key for the control of the stereoselectivity. The nucleophilic epoxidation of methyl 2-methylene-3-tert-butyldimethylsilyloxycarboxylate esters has been recently reported by A. Myers to get the anti diastereomer with high selectivity ${ }^{12}$ (Scheme 1). The epoxidation of Morita-Baylis-Hillman adducts is an interesting transformation because the resulting epoxides can be used in the total synthesis of interesting natural products. ${ }^{10-12}$ We now report a study of the stereoselectivity of the nucleophilic epoxidation of $\beta$-hydroxy- $\alpha$-methylene esters.

## Results and discussion

We wanted to study the selectivity of epoxidation of 3-hydroxy-methylene carboxylate esters with a range of R alkyl and aryl groups (Scheme 2). For the preparation of the substrates, a comparison of different experimental procedures was performed as shown in Table 1. Most of the substrates were prepared in good yield using DABCO as a base and a (1:1) mixture of dioxane:water as reported. ${ }^{13}$ We obtained higher yields when the reaction was performed at higher concentrations ( 10 M ) than reported (see experimental section). Compounds $\mathbf{1 i}$ and $\mathbf{1} \mathbf{j}$ were
obtained in best yields under solvent-free conditions and longer period of time, and compounds $\mathbf{1 m}$ and $\mathbf{1 n}$ were prepared using dimethylsulfoxide as a solvent.

Esters 1 were epoxidized using lithium tert-butylperoxide (2 equivalents) as the oxidizing reagent in THF as solvent at $-20^{\circ} \mathrm{C} .{ }^{2,8,9}$ Table 2 shows that the $\mathbf{2}$ syn isomer was the major product in all cases. For the aliphatic series (compounds 1a-f), the higher steric volume of the R pendant alkyl group the higher stereoselectivity is observed (entries 1-6). When the R is an alkenyl group then the epoxidation reaction is not stereoselective (entry 7). Compounds $\mathbf{1} \mathbf{h}$-s having an aromatic group gave the corresponding syn isomer $\mathbf{2}$ in very good selectivity.

We also epoxidized compound $\mathbf{1 h}$ by using oxidants other than lithium tert-butylperoxide (Table 3). If the reaction was carried out using tert-butyl hydrogenperoxide in the presence of substoichiometric amount of base (entry 1), then a slightly lower selectivity was observed compared to the reaction carried out using a stoichiometric amount of oxidant (entry 8, Table 2). Lithium cumylperoxide gave similar result to lithium tert-butylperoxide (entry 2). On the other hand, in the alkaline peroxides series, potassium gave poorer stereoselectivity than either lithium or sodium (entries 1 and 6-8). The yield of the epoxidation using $m$-CPBA (entry 3) was low at room temperature but it
increased at higher temperature (entry 4), affording the syn isomer as the major one. When $m$-CPBA was used in the presence of potassium carbonate ${ }^{14}$ (entry 5), only starting material was recovered.

The stereochemistry of epoxides $\mathbf{2 b}$ and $\mathbf{2 h}$ was confirmed by comparison with already reported data. ${ }^{12,15}$ The epoxyesters 2d, 3d, 2e and 3e were transformed into cyclic carbonates through a one-pot sequence: treatment with thiophenol in the presence of a base which resulted in the opening of the oxirane ring and then addition of triphosgene to give carbonates $\mathbf{4 , 5 , 6}$ and $\mathbf{7}$, respectively (Scheme 3). The stereochemical assignment of the carbonates was performed by NOE experiments (Scheme 3). Carbonates $\mathbf{4}$ and $\mathbf{6}$ gave NOE between H-5 and methyl ester whilst 5 and $\mathbf{7}$ gave NOE between H-5 and methylene from the (phenylthio)methyl group.

Scheme 3. Cyclic carbonates 4-7.

## Conclusions

In summary, the diastereoselectivity of the nucleophilic epoxidation of 3-hydroxy-2-methylene esters has been studied. The syn isomer was the major one in all cases. The resulting 3-hydroxy 2 -epoxyesters were treated with thiophenol for transformation into 2,3-dihydroxy-2-((phenylthio)methyl) which upon treatment with triphosgene afforded the corresponding cyclic carbonates.

## Experimental Section

General Experimental Methods. All solvents used in reactions were freshly distilled from appropriate drying agents before use. ${ }^{1} \mathrm{H}$ NMR spectra and ${ }^{13} \mathrm{C}$ NMR spectra were measured in $\mathrm{CDCl}_{3}\left({ }^{1} \mathrm{H}, 7.24 \mathrm{ppm} ;{ }^{13} \mathrm{C} 77.0 \mathrm{ppm}\right)$ solution at $30^{\circ} \mathrm{C}$ on a 300 MHz or a 500 MHz NMR spectrometer. IR spectra were recorded as oil films or KBr discs or NaCl pellets on a FT-IR spectrometer. EM Science Silica Gel 60 was used for column chromatography while TLC was
performed with precoated plates (Kieselgel 60, $\mathrm{F}_{254}, 0.25 \mathrm{~mm}$ ). Unless otherwise specified, all reactions were carried out under argon atmosphere with magnetic stirring.

## General experimental procedure for the preparation of compounds 1a-s:

To a solution of aldehyde ( 1 mmol ) in dioxane-water (1:1) ( 0.1 mL ) was added methyl acrylate ( 3 mmol ) and DABCO ( 1 mmol ). The reaction was monitored by TLC. Upon completion, water ( 70 mL ) was added and poured onto a separatory funnel and extracted with ethyl ether or dichloromethane ( $3 \times 30 \mathrm{~mL}$ ), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, filtered, and concentrated under reduced pressure. The crude was purified through chromatography (silicagel, hexanes/ethyl acetate (8:2), (6:4)) to afford the desired compound.

To a $-78{ }^{\circ} \mathrm{C}$ cold THF ( 3.5 mL ) was added TBHP ( 3.3 M in toluene) ( 2 mmol ) and then methyllithium ( 1.6 M in hexanes) ( 1.7 mmol ). The resulting mixture was stirred at $-78{ }^{\circ} \mathrm{C}$ for 15 min and then a solution of compound $\mathbf{1}$ (1 mmol ) in THF ( 2 mL ) was added drop wise and then the mixture was left at $-20^{\circ} \mathrm{C}$ (fridge) for 20 h . Then solid $\mathrm{Na}_{2} \mathrm{SO}_{3}(120 \mathrm{mg})$ was added in one portion and stirred for 15 min , then diluted with water and extracted with $\mathrm{Et}_{2} \mathrm{O}$ (3 x 30 mL ), the organic layers were washed (brine), dried $\left(\mathrm{Na}_{2} \mathrm{SO}_{4}\right)$, and concentrated. The crude oil was purified through chromatography (silica-gel, hexanes/EtOAc (7:3) and (1:1)).

## General experimental procedure for the preparation of cyclic carbonates:

An ice-bath cold suspension of sodium hydride ( $60 \%$ in mineral oil) ( 1.12 mmol ) in THF ( 1 mL ) was treated with
thiophenol ( 2.25 mmol ). The mixture was stirred at room temperature for 15 min and then a solution of the epoxyester $2(0.75 \mathrm{mmol})$ in THF ( 1 mL ) was added drop wise and the mixture was stirred at room temperature for 1.5 h . Then was treated with pyridine $(0.22 \mathrm{mmol})$ and triphosgene $(0.48 \mathrm{mmol})$. The mixture was refluxed for 15 h . Then brine was added and extracted with $\mathrm{Et}_{2} \mathrm{O}(3 \times 20 \mathrm{~mL})$, the organic layers were washed (brine), dried $\left(\mathrm{Na}_{2} \mathrm{SO}_{4}\right)$, and concentrated. The crude oil was purified through chromatography (silica-gel, hexanes/EtOAc (8:2) and (7:3)).
