Pest categorisation of *Anthonomus signatus*

EFSA Panel on Plant Health (PLH),
Michael Jeger, Claude Bragard, David Caffier, Thierry Candresse, Elisavet Chatzivassiliou, Katharina Dehnen-Schmutz, Gianni Gilioli, Jean-Claude Gregoire, Josep Anton Jaques Miret, Maria Navajas Navarro, Björn Niere, Stephen Parnell, Roel Potting, Trond Rafoss, Vittorio Rossi, Gregor Urek, Ariena Van Bruggen, Wopke Van der Werf, Jonathan West, Stephan Winter, Ewelina Czwienckez, Mitesha Aukhojee and Alan MacLeod

**Abstract**

The Panel on Plant Health performed a pest categorisation of the strawberry bud weevil, *Anthonomus signatus* Say, (Coleoptera: Curculionidae), for the EU. *A. signatus* is a well-defined and distinguishable species, recognised as a pest of strawberry (*Fragaria*) fruit production in eastern North America where it is also a pest of *Rubus*. There are reports of *A. signatus* associated with non-rosaceous plants such as *Mentha*, *Nepeta*, *Rhododendron* and *Solidago* although whether such plants are true hosts is uncertain. This pest categorisation focuses on *Fragaria* and *Rubus* as hosts. *Anthonomus signatus* is not known to occur in the EU. It is listed in Annex IIAI of Council Directive 2000/29/EC. The international trade in *Fragaria* and *Rubus* plants for planting provides a potential pathway to introduce *A. signatus* from North America. Considering climatic similarities between North America and the EU, the thermal biology of *A. signatus* and host distribution in the EU, *A. signatus* has the potential to establish within the EU. There would be one generation per year, as in North America. As a pest of field grown *Fragaria* and *Rubus*, *A. signatus* would not be expected to establish in EU glasshouses. In North America, adults clip developing buds, preventing fruit development and reducing yield. Losses are variable and depend on the cultivars attacked. Severe crop losses have been reported. However, some *Fragaria* cultivars can compensate the loss of buds, e.g. by increasing the weight of fruits developing on remaining buds. Phytosanitary measures are available to reduce the likelihood of introduction of *A. signatus* from North America. All criteria assessed by EFSA for consideration as a potential Union quarantine pest are met. As *A. signatus* is not known to occur in the EU, this criterion assessed by EFSA to consider it as a Union regulated non-quarantine pest is not met.

1. Introduction

1.1. Background and Terms of Reference as provided by the requestor

1.1.1. Background

Council Directive 2000/29/EC on protective measures against the introduction into the Community of organisms harmful to plants or plant products and against their spread within the Community establishes the present European Union plant health regime. The Directive lays down the phytosanitary provisions and the control checks to be carried out at the place of origin on plants and plant products destined for the Union or to be moved within the Union. In the Directive’s 2000/29/EC annexes, the list of harmful organisms (pests) whose introduction into or spread within the Union is prohibited, is detailed together with specific requirements for import or internal movement.

Following the evaluation of the plant health regime, the new basic plant health law, Regulation (EU) 2016/2031 on protective measures against pests of plants, was adopted on 26 October 2016 and will apply from 14 December 2019 onwards, repealing Directive 2000/29/EC. In line with the principles of the above mentioned legislation and the follow-up work of the secondary legislation for the listing of EU regulated pests, EFSA is requested to provide pest categorizations of the harmful organisms included in the annexes of Directive 2000/29/EC, in the cases where recent pest risk assessment/ pest categorisation is not available.

1.1.2. Terms of Reference

EFSA is requested, pursuant to Article 22(5.b) and Article 29(1) of Regulation (EC) No 178/2002, to provide scientific opinion in the field of plant health.

EFSA is requested to prepare and deliver a pest categorisation (step 1 analysis) for each of the regulated pests included in the appendices of the annex to this mandate. The methodology and template of pest categorisation have already been developed in past mandates for the organisms listed in Annex II Part A Section II of Directive 2000/29/EC. Slight changes have been made to the template to better align with Regulation 2016/2031.

The list of the harmful organisms included in the annex to this mandate comprises 133 harmful organisms or groups. A pest categorisation is expected for these 133 pests or groups and the delivery of the work would be stepwise at regular intervals through the year as detailed below. First priority covers the harmful organisms included in Appendix 1, comprising pests from Annex II Part A Section I and Annex II Part B of Directive 2000/29/EC. The delivery of all pest categorisations for the pests included in Appendix 1 is June 2018. The second priority is the pests included in Appendix 2, comprising the group of Cicadellidae (non-EU) known to be vector of Pierce’s disease (caused by *Xylella fastidiosa*), the group of Tephritidae (non-EU), the group of potato viruses and virus-like organisms, the group of viruses and virus-like organisms of *Cydonia* Mill., *Fragaria* L., *Pyrus* L., *Ribes* L., *Rubus* L. and *Vitis* L. and the group of Margarodes (non-EU species). The delivery of all pest categorisations for the pests included in Appendix 2 is end 2019. The pests included in Appendix 3 cover pests of Annex I part A section I and all pests categorisations should be delivered by end 2020.

For the above mentioned groups, each covering a large number of pests, the pest categorisation will be performed for the group and not the individual harmful organisms listed under ‘such as’ notation in the Annexes of the Directive 2000/29/EC. The criteria to be taken particularly under consideration for these cases, is the analysis of host pest combination, investigation of pathways, the damages occurring and the relevant impact.

Finally, as indicated in the text above, all references to ‘non-European’ should be avoided and replaced by ‘non-EU’ and refer to all territories with exception of the Union territories as defined in Article 1 point 3 of Regulation (EU) 2016/2031.

1.1.2.1. Terms of Reference: Appendix 1

List of harmful organisms for which pest categorisation is requested. The list below follows the annexes of Directive 2000/29/EC.
Annex IIAI

(a) Insects, mites and nematodes, at all stages of their development

- Aleurocanthus spp.
- Anthonomus biglifer (Schenkling)
- Anthonomus signatus (Say)
- Aschistonyx eppoi Inouye
- Carposina niponensis Walsingham
- Enormania packardi (Zeller)
- Enormania pruniwora Walsh
- Grapholita inopinata Heinrich
- Hismomonus phycitis
- Leucaspis japonica Ckll.
- Listronotus bonariensis (Kuschel)
- Aleurocanthus spp.
- Numonia pyrivorella (Matsumura)
- Anthonomus bisignifer (Schenkling)
- Oligonychus perditus Pritchard and Baker
- Anthonomus signatus (Say)
- Pissodes spp. (non-EU)
- Aschistonyx eppoi Inouye
- Scirtothrips aurantii Faure
- Carposina niponensis Walsingham
- Scirtothrips citri (Moultex)
- Enormania packardi (Zeller)
- Scolytidae spp. (non-EU)
- Enormania pruniwora Walsh
- Scrobipalpopsis solanivora Povolny
- Grapholita inopinata Heinrich
- Tachypterellus quadrigibbus Say
- Hismomonus phycitis
- Toxoptera citricida Kirk.
- Leucaspis japonica Ckll.
- Unaspis citri Comstock

(b) Bacteria

- Citrus variegated chlorosis
- Erwinia stewartii (Smith) Dye
- Xanthomonas campestris pv. oryzae (Ishiyama)
- Dye and pv. oryzicola (Fang. et al.) Dye

(c) Fungi

- Alternaria alternata (Fr.) Keissler (non-EU pathogenic isolates)
- Anisogramma anomala (Peck) E. Müller
- Apiosporina morbosa (Schwein.) v. Arx
- Ceratocystis virescens (Davidson) Moreau
- Cercospora pini-densiflorae (Hori and Nambu)
- Deighton
- Cercospora angolensis Carv. and Mendes
- Elsinoe spp. Bitanc. and Jenk. Mendes
- Fusarium oxysporum f. sp. albedinis (Kilian and Maire) Gordon
- Guignardia piricola (Nosa) Yamamoto
- Puccinia pittieriana Hennings
- Stegophora ulmea (Schweinitz: Fries) Sydow & Sydow
- Venturia nashicola Tanaka and Yamamoto

(d) Virus and virus-like organisms

- Beet curly top virus (non-EU isolates)
- Black raspberry latent virus
- Blight and blight-like
- Cadang-Cadang viroid
- Citrus tristeza virus (non-EU isolates)
- Leprosis
- Little cherry pathogen (non-EU isolates)
- Naturally spreading psorosis
- Palm lethal yellowing mycoplasm
- Satsuma dwarf virus
- Tatter leaf virus
- Witches’ broom (MLO)

Annex IIB

(a) Insect mites and nematodes, at all stages of their development

- Anthonomus grandis (Boh.)
- Cephalcia lariiciphila (Klug)
- Dendroctonus micans Kugelan
- Gilphinia hercyniae (Hartig)
- Gonipterus scutellatus Gyll.
- Ips amitinus Eichhof
- Ips cembrae Heer
- Ips duplicatus Sahlberg
- Ips sexdentatus Börner
- Ips typographus Heer
- Sternochetus mangiferarum Fabricius

(b) Bacteria

- Curtobacterium flaccumfaciens pv. flaccumfaciens (Hedges) Collins and Jones

(c) Fungi

- Glomerella gossypii Edgerton
- Hypoxylon mammatum (Wahl.) J. Miller
- Gremmeniella abietina (Lag.) Morelet
- Hypoxylon mammatum (Wahl.) J. Miller
- Glomerella gossypii Edgerton
1.1.2.2. Terms of Reference: Appendix 2

List of harmful organisms for which pest categorisation is requested per group. The list below follows the categorisation included in the annexes of Directive 2000/29/EC.

**Annex IAI**

*(a) Insects, mites and nematodes, at all stages of their development*

Group of Cicadellidae (non-EU) known to be vector of Pierce’s disease (caused by *Xylella fastidiosa*), such as:

1) *Carneocephala fulgida* Nottingham
2) *Draeculacephala minerva* Ball

Group of Tephritidae (non-EU) such as:

1) *Anastrepha fraterculus* (Wiedemann)
2) *Anastrepha ludens* (Loew)
3) *Anastrepha obliqua* Macquart
4) *Anastrepha suspensa* (Loew)
5) *Dacus ciliatus* Loew
6) *Dacus curcurbitae* Coquillet
7) *Dacus dorsalis* Hendel
8) *Dacus tryoni* (Froggatt)
9) *Dacus tsuneonis* Miyake
10) *Dacus zonatus* Saund.
11) *Epochra canadensis* (Loew)

*(c) Viruses and virus-like organisms*

Group of potato viruses and virus-like organisms such as:

1) Andean potato latent virus
2) Andean potato mottle virus
3) Arracacha virus B, oca strain
4) Potato black ringspot virus
5) Potato virus T
6) non-EU isolates of potato viruses A, M, S, V, X and Y (including Yo, Yn and Yc) and Potato leafroll virus

Group of viruses and virus-like organisms of Cydonia Mill., Fragaria L., Malus Mill., Prunus L., Pyrus L., Ribes L., Rubus L. and Vitis L., such as:

1) Blueberry leaf mottle virus
2) Cherry rasp leaf virus (American)
3) Peach mosaic virus (American)
4) Peach phony rickettsia
5) Peach rosette mosaic virus
6) Peach rosette mycoplasma
7) Peach X-disease mycoplasma
8) Peach yellows mycoplasma
9) Plum line pattern virus (American)
10) Raspberry leaf curl virus (American)
11) Strawberry witches’ broom mycoplasma
12) Non-EU viruses and virus-like organisms of *Cydonia Mill., Fragaria L., Malus Mill., Prunus L., Pyrus L., Ribes L., Rubus L. and Vitis L.*

**Annex IIAI**

*(a) Insects, mites and nematodes, at all stages of their development*

Group of *Margarodes* (non-EU species) such as:

1) *Margarodes vitis* (Phillipi)
2) *Margarodes prieskaensis* Jakubski
3) *Margarodes vredendalensis* de Klerk

1.1.2.3. Terms of Reference: Appendix 3

List of harmful organisms for which pest categorisation is requested. The list below follows the annexes of Directive 2000/29/EC.
Annex IAI

(a) Insects, mites and nematodes, at all stages of their development

Acleris spp. (non-EU)  Longidorus diadecturus  Eveleigh and Allen
Amauromyza maculosa (Malloch)  Monochamus spp. (non-EU)
Anomalus orientalis Waterhouse  Myndus crudus  Van Duzee
Arrhenodes minutus Drury  Nacobbus aberrans (Thorne) Thorne and Allen
Choristoneura spp. (non-EU)  Naupactus leucoloma Boheman
Conotrachelus nenuhar (Herbst)  Premnotypes spp. (non-EU)
Dendrolimus sibiricus Tscheterikov  Pseudopityophthorus minutissimus (Zimmermann)
Diabrotica barberi Smith and Lawrence  Pseudopityophthorus pruinosus (Eichhoff)
Diabrotica undecimpunctata howardi Barber  Scaphoideus luteolus (Van Duzee)
Diabrotica undecimpunctata undecimpunctata  Spodoptera eridania (Cramer)
Mannerheim
Diabrotica virgifera zeae Krysan & Smith  Spodoptera frugiperda (Smith)
Diaphorina citri Kuway  Spodoptera litura (Fabricus)
Heliothis zea (Boddie)  Thrips palmi Karny
Hirschmanniella spp., other than  Xiphinema americanum Cobb sensu lato (non-EU)
Hirschmanniella gracilis (de Man) Luc and Gooyde  populations
Liriomyza sativae Blanchard  Xiphinema californicum Lamberti and Bleve-Zacheo

(b) Fungi

Ceratocystis fagacearum (Bretz) Hunt  Mycosphaerella larici-leptolepis Ito et al.
Chrysomyxa arctostaphyli Dietel  Mycosphaerella populorum G. E. Thompson
Cronartium spp. (non-EU)  Phoma andina Turkensteen
Endocronartium spp. (non-EU)  Phyllosticta solitaria Ell. and Ev.
Guignardia laricina (Saw.) Yamamoto and Ito  Septoria lycopersici Spec. var. malagutii Ciccarone
Gymnosporangium spp. (non-EU)  and Boerema
Inonotus weirii (Murril) Kotlaba and Pouzar  Thecaphora solani Barrus
Melampsora farlowii (Arthur) Davis  Trechispora brinkmannii (Bresad.) Rogers

(c) Viruses and virus-like organisms

Tobacco ringspot virus  Pepper mild tigré virus
Tomato ringspot virus  Squash leaf curl virus
Bean golden mosaic virus  Euphorbia mosaic virus
Cowpea mild mottle virus  Florida tomato virus
Lettuce infectious yellows virus

(d) Parasitic plants

Arceuthobium spp. (non-EU)

Annex IAII

(a) Insects, mites and nematodes, at all stages of their development

Meloidogyne fallax Karssen  Rhizoecus hibisci Kawai and Takagi
Popillia japonica Newman

(b) Bacteria

Clavibacter michiganensis (Smith) Davis et al.  Ralstonia solanacearum (Smith) Yabuuchi et al.
ssp. sepedonicus (Spieckermann and Kotthoff)  Davis et al.

(c) Fungi

Melampsora medusae Thümén  Synchytrium endobioticum (Schilbersky) Percival
Annex IB

(a) Insects, mites and nematodes, at all stages of their development
Leptinotarsa decemlineata Say Liriomyza bryoniae (Kaltenbach)

(b) Viruses and virus-like organisms
Beet necrotic yellow vein virus

1.2. Interpretation of the Terms of Reference

Anthonomus signatus is one of a number of pests listed in the Appendices to the Terms of Reference (ToR) to be subject to pest categorisation to determine whether it fulfils the criteria of a quarantine pest or those of a regulated non-quarantine pest (RNQP) for the area of the European Union (EU) excluding Ceuta, Melilla and the outermost regions of Member States referred to in Article 355(1) of the Treaty on the Functioning of the European Union (TFEU), other than Madeira and the Azores.

2. Data and methodologies

2.1. Data

2.1.1. Literature search

A search of literature (1997–2017) in Web of Science and Scopus was conducted at the beginning of the categorisation. The search focussed on A. signatus and its geographic distribution, life cycle, host plants and the damage it causes. The following search terms (TS) and combinations were used:

TS = ("Anthonomus signatus" OR "Strawberry bud weevil") AND TS = (geograph* OR distribution OR "life cycle" OR lifecycle OR host OR hosts OR plant* OR damag*)

Further references and information were obtained from experts, from citations within the references and grey literature.

2.1.2. Database search

Pest information, on host(s) and distribution, was retrieved from the EPPO Global Database (EPPO 2017)

Data about import of commodity types that could potentially provide a pathway for the pest to enter the EU were obtained from EUROSTAT and from the EU Seventh Framework Programme project ISEFOR (Increasing Sustainability of European Forests, 2007–2013 KBBE 2009-3 grant agreement 245268). The ISEFOR project examined the plant nursery trade and, for some EU Member States, collected import data on plants for planting at a much more detailed level than is made publically available via EUROSTAT. While it is recognised that the ISEFOR data is not comprehensive, it does contain some data on imports of plants for planting of A. signatus hosts, such as Fragaria and Rubus.

Statistics about the area of hosts grown in the EU were obtained from EUROSTAT.

2.2. Methodologies

The Panel performed the pest categorisation for A. signatus following guiding principles and steps presented in the EFSA guidance on the harmonised framework for pest risk assessment (EFSA PLH Panel, 2010) and as defined in the International Standard for Phytosanitary Measures No 11 (FAO, 2013) and No 21 (FAO, 2004).

In accordance with the guidance on a harmonised framework for pest risk assessment in the EU (EFSA PLH Panel, 2010), this work was initiated following an evaluation of the EU’s plant health regime. Therefore, to facilitate the decision-making process, in the conclusions of the pest categorisation, the Panel addresses explicitly each criterion for a Union quarantine pest and for a Union RNQP in accordance with Regulation (EU) 2016/2031 on protective measures against pests of plants, and includes additional information required as per the specific terms of reference received by the European Commission. In addition, for each conclusion, the Panel provides a short description of its associated uncertainty.

Table 1 presents the Regulation (EU) 2016/2031 pest categorisation criteria on which the Panel bases its conclusions. All relevant criteria have to be met for the pest to qualify either as a
quarantine pest or as a RNQP. If one of the criteria is not met, the pest will not qualify. In such a case, the working group should consider the possibility to terminate the assessment early and be concise in the sections preceding the question for which the negative answer is reached. Note that a pest that does not qualify as a quarantine pest may still qualify as a regulated non-quarantine pest which needs to be addressed in the opinion. For the pests regulated in the protected zones only, the scope of the categorisation is the territory of the protected zone, thus the criteria refer to the protected zone instead of the EU territory.

It should be noted that the Panel’s conclusions are formulated respecting its remit and particularly with regards to the principle of separation between risk assessment and risk management (EFSA founding regulation); therefore, instead of determining whether the pest is likely to have an unacceptable impact, the Panel will present a summary of the observed pest impacts. Economic impacts are expressed in terms of yield and quality losses and not in monetary terms, while addressing social impacts is outside the remit of the Panel, in agreement with EFSA guidance on a harmonised framework for pest risk assessment (EFSA PLH Panel, 2010).

Table 1: Pest categorisation criteria under evaluation, as defined in Regulation (EU) 2016/2031 on protective measures against pests of plants (the number of the relevant sections of the pest categorisation is shown in brackets in the first column)

<table>

<td>Is the identity of the pest established, or has it been shown to produce consistent symptoms and to be transmissible?</td>
<td>Is the identity of the pest established, or has it been shown to produce consistent symptoms and to be transmissible?</td>
</tr>
<tr>
<td>Absence/presence of the pest in the EU territory (Section 3.2)</td>
<td>Is the pest present in the EU territory? If present, is the pest widely distributed within the EU? Describe the pest distribution briefly!</td>
<td>Is the pest present in the EU territory? If not, it cannot be a protected zone quarantine organism.</td>
<td>Is the pest present in the EU territory? If not, it cannot be a regulated non-quarantine pest. (A regulated non-quarantine pest must be present in the risk assessment area).</td>
</tr>
<tr>
<td>Regulatory status (Section 3.3)</td>
<td>If the pest is present in the EU but not widely distributed in the risk assessment area, it should be under official control or expected to be under official control in the near future.</td>
<td>The protected zone system aligns with the pest free area system under the International Plant Protection Convention (IPPC). The pest satisfies the IPPC definition of a quarantine pest that is not present in the PRA area (i.e. protected zone).</td>
<td>Is the pest regulated as a quarantine pest? If currently regulated as a quarantine pest, are there grounds to consider its status could be revoked?</td>
</tr>
<tr>
<td>Pest potential for entry, establishment and spread in the EU territory (Section 3.4)</td>
<td>Is the pest able to enter into, become established in, and spread within, the EU territory? If yes, briefly list the pathways!</td>
<td>Is the pest able to enter into, become established in, and spread within, the protected zone areas? Is entry by natural spread from EU areas where the pest is present possible?</td>
<td>Is spread mainly via specific plants for planting, rather than via natural spread or via movement of plant products or other objects? Clearly state if plants for planting is the main pathway!</td>
</tr>
</tbody>
</table>

The Panel will not indicate in its conclusions of the pest categorisation whether to continue the risk assessment process, but, following the agreed two-step approach, will continue only if requested by the risk managers. However, during the categorisation process, experts may identify key elements and knowledge gaps that could contribute significant uncertainty to a future assessment of risk. It would be useful to identify and highlight such gaps so that potential future requests can specifically target the major elements of uncertainty, perhaps suggesting specific scenarios to examine.

### 3. Pest categorisation

#### 3.1. Identity and biology of the pest

##### 3.1.1. Identity and taxonomy

<table>

</table>

*A. signatus* Say, 1831 is an insect in the Order Coleoptera (beetles) and the family Curculionidae (weevils). Clark (1991) provides a key to the *Anthonomus-Curvirostris* species group which includes *A. signatus*.

Three junior synonyms are known, *Anthonomus bisignatus* Gyllenhal, 1836; *Anthonomus pallidus* Dietz, 1891; and *Anthonomus scutellatus* Gyllenhal, 1836.

##### 3.1.2. Biology of the pest

*A. signatus* has one generation per year. Adults can overwinter beneath strawberry plants and plant debris within fields, although most literature reports adults overwintering within the vegetation of
adjacent field boundaries and under plant debris in wooded areas (Metcalf and Metcalf, 1993; Smith et al., 1997; Kovach et al., 1999). Adults emerge in the spring and can be found when daytime temperatures are consistently over 16°C, typically from mid-March in the southern USA to mid-May in Canada, coinciding with those hosts that have early season bud development (Schaefer, 1978 – cited by Mailloux and Bostanian, 1993; Metcalf and Metcalf, 1993; McPhie and Burrell, 2016). The weevils emerge in spring and feed on young leaves of *Fragaria* and *Rubus* and possibly other plants, but most extensively on their flower buds, which provide them the necessary pollen to reach sexual maturity. Afterwards, adults mate and females search for *Fragaria* and *Rubus* plants to oviposit and continue feeding.

An adult gravid female will chew a hole in the side of an unopened host flower bud then deposit an egg in the hole. She will then eat about halfway through the pedicel, between 3 and 6 mm below the bud, partially severing the bud from the stem, creating the bud clip effect. This prevents the bud from further development and provides a protected environment for the egg to hatch and for a larva to develop within. The bud can hang from the plant for a few days but will eventually wilt and drop to the ground (Clarke & Howitt, 1975; Mailloux and Bostanian, 1993; Kovach et al., 1999). Each female can lay about 80 eggs, depending on the temperature and they can be seen mating throughout the oviposition period (Baerg, 1923; cited in Smith et al., 1997).

Most feeding occurs at field edges (Campbell et al., 1989; Kovach et al., 1993 in Kovach et al., 1999) up to 15 m in from the field edge (Handley and Dill, 2009) suggesting that adults do not move far or quickly. Foord et al. (2017) reported that *A. signatus* rarely fly or walk more than 30 feet (approx. 10 m) while looking for food or places to lay eggs.

The egg hatches in 6–14 days and the larva feeds on the immature pollen within the bud for 3–4 weeks. There are three larval instars (Mailloux and Bostanian, 1993). Even when the buds are completely severed from the plant, the buds contain enough nutrients for larvae to complete their development. Pupation occurs within the dry bud and takes 5–8 days. Adult weevils emerge during May and June and feed for a few weeks on pollen and flower petals before searching for overwintering sites in late July and August (Baerg, 1923; cited in Sorensen, 1993; Smith et al., 1997).

On cool, cloudy days, the adults are slow-moving but in bright warm conditions they can fly short distances (Smith et al., 1997; CSL, 1998).

### 3.1.3. Detection and identification of the pest

**Are detection and identification methods available for the pest?**

Yes, the organism can be detected by visual searching, often after damage symptoms are seen. The species can be identified by examining morphological features, for which keys exist, e.g. Ahmad and Burke (1972); Burke (1968) and Clark (1991).

In North America, there are no generally accepted sampling techniques to monitor for *A. signatus* (Bostanian et al., 1999). Methods, such as the sticky traps, pheromone traps, sweep nets and beat cloths, to monitor *A. signatus* are not effective at predicting population size or bud damage (Howard, 2007). In regions with a history of *A. signatus* damage, monitoring for bud damage should begin at the time of bud emergence and continue once or twice weekly throughout the period of flowering (Handley and Dill, 2009).

*A. signatus* is noticed when the damage symptoms (clipped buds) are detected, either hanging from the plants or laying on the ground.

- Eggs are 0.5 mm long, glassy-white.
- Larvae are 3–4 mm long, off-white becoming greyish with age. They remain in the bud to pupate.
- Pupa are yellowish-white (2–3 mm x 1–2 mm).

Larva and pupa of *A. signatus* are well described, keyed by Ahmad and Burke (1972). Adults are about 2.5 mm long. The head is brownish black with an elongated curved rostrum. The elytrae are pale brown to dark reddish brown. A large black spot is often present on each elytron although some adults do not have these spots. Legs are brown. Careful examination is required to reliably distinguish adult and immature stages of these species from those of *Anthonomus rubi*, the strawberry blossom weevil, which occurs in Europe (CSL, 1998).
3.2. Pest distribution

3.2.1. Pest distribution outside the EU

*Anthonomus signatus* is only present in North America and has not been reported in the EU (Smith et al., 1997; EPPO Global database, 2017; Figure 1 and Table 2).

![Figure 1: Global distribution map for Anthonomus signatus (extracted from EPPO global database accessed on 20 March 2017)](image)

3.2.2. Pest distribution in the EU

Is the pest present in the EU territory? If present, is the pest widely distributed within the EU?

No, *Anthonomus signatus* is not known to occur in the EU.

3.3. Regulatory status

3.3.2. Legislation addressing plants and plant parts on which *Anthonomus signatus* is regulated

Table 4: Regulated hosts and commodities that may involve *Anthonomus signatus* in Annexes III, IV and V of Council Directive 2000/29/EC

</tr>
</tbody>
</table>

3.4. Entry, establishment and spread in the EU

3.4.1. Host range

Much North American literature refers to *A. signatus* as a pest primarily of strawberry (*Fragaria*) but it is also known as a pest of *Rubus* fruit such as blackberry (*Rubus fruticosus*), black raspberry (*Rubus idaeus*), and red raspberry (*Rubus idaeus*).
occidentalis), dewberry (a group of species in the genus *Rubus*, closely related to the blackberries) and raspberry (*Rubus idaeus*).

Campbell et al. (1989) records earlier literature that reports *A. signatus* occurring on redbud (*Cercis* sp.), rhododendron (*Rhododendron* sp.), rambler rose (*Rosa multiflora*), cinquefoil (*Potentilla* sp.), apple (*Malus* sp.), milkweed (*Asclepias* sp.), goldenrod (*Solidago* sp.), basswood (*Tilia americana*), wild bergamot (*Monarda fistulosa*), mint (*Mentha* sp.), catnip (*Nepeta cataria*) and heal-all (*Prunella vulgaris*). Whether these are true hosts on which the organism can complete its life cycle is unknown. CABI (2017) regard such reports as incidental occurrences. This categorisation will focus on *Fragaria* and *Rubus* because these are the hosts which the US and Canadian literature reports feeding damage and life stage development on.

Current EU legislation (2000/29/EC) only regulates *A. signatus* on *Fragaria* plants for planting, other than seed. However, as noted above, *A. signatus* does have other hosts, at least within the genus *Rubus*. Given that imports of *Rubus* plants for planting are permitted from the USA and Canada, *A. signatus* could potentially be carried into the EU via pathways other than *Fragaria* plants for planting.

### 3.4.2. Entry

**Is the pest able to enter into the EU territory?**

Yes, *A. signatus* could potentially enter the EU at least via *Fragaria* and *Rubus* plants for planting.

The EU can import *A. signatus* host plants for planting from North America, including from regions where the pest occurs. ‘Green’ strawberry plants are field grown plants grown to be transplanted as plants for planting for fruit production. Rooted plants can be traded in bags with or without growing medium. Due to the growing and shipping conditions, such plants could potentially be contaminated by a range of pests, including *A. signatus* (EPPO, 2008).

International trade statistics describing the trade in plants for planting are not sufficiently detailed as to allow for the amount of trade in individual plant species to be determined. The CN code that includes strawberry plants for planting is 0602 90 30 (vegetable and strawberry plants). A search of EUROSTAT indicated that there were no EU imports of CN 0602 90 30 materials from Canada during the period 2010–2015; however, there were imports from the USA, shown below in Table 5:

**Table 5:** EU imports of vegetable and strawberry plants (CN 0602 90 30) from the USA 2010–2015 (hundreds of kilograms) (Source: EUROSTAT accessed 20/3/2017)

<table>
<thead>

</tr>
</tbody>
</table>

Although EUROSTAT cannot be used to distinguish strawberry plants from vegetable plants for planting, data collected during the ISEFOR project indicate that there was international movement of strawberry plants for planting from the USA into the EU between 2000 and 2012 hence a possible pathway for entry exists (Table 6).

*Rubus* spp. plants for planting can also be imported from North America into the EU. *Rubus* plants for planting are categorised within CN imports code CN 0602 2090 (trees, shrubs and bushes, grafted or not, of kinds which bear edible fruit or nuts (excl. vine slips)).

**Table 6:** EU MS imports of CN 0602 2090 (trees, shrubs and bushes, grafted or not, of kinds which bear edible fruit or nuts) from the USA and Canada. An unknown proportion of these imports could be *Rubus* (hundreds of kilograms)

ISEFOR data indicate that there have been imports of *Rubus* plants for planting from the USA into the EU. Field grown *Rubus* plants grown in the USA or Canada to be shipped to the EU and transplanted for fruit production could potentially be contaminated by a range of pests, including *A. signatus* (Smith et al., 1997).
A. signatus is not known to have spread or been introduced anywhere outside of its native distribution within the eastern USA and Canada.

Up to March 2017, there were zero records of interception of A. signatus in the Europhyt database.

### 3.4.3. Establishment

**Is the pest able to become established in the EU territory?**

*Yes*, biotic factors (host availability) and abiotic factors (climate suitability) suggest that A. signatus would find large parts of the EU suitable for establishment.

#### 3.4.3.1. EU distribution of main host plants

A global distribution map of the area of strawberry harvest is provided as Figure 2, available at CAPRA project website. The map is based on Monfreda et al. (2008) with additional data handling conducted during the EU funded project PRATIQUE (Baker, 2012). The maximum in the legend (dark green) represents the top 5% of the world strawberry distribution (the 95% quantile).

![Figure 2: Global distribution of the density of harvested strawberry (ha crop/km²) (source CAPRA database accessed on 20 March 2017)](image)

As indicated in Figure 2, some of the world’s greatest density of strawberry production occurs in Europe. Table 7 indicates the top three EU countries of strawberry production by area harvested, together with total EU area. Poland grows the largest area of strawberries of any other EU MS. Approximately 70% of the annual area of EU strawberry production occurs in Poland, Germany and Spain. Typically, approximately half of the total EU strawberry area is usually grown in Poland.

**Table 7:** EU area of strawberry production 2011-2015 (thousands of hectares) ranked by area

3.4.3.2. Climatic conditions affecting establishment

*A. signatus* is distributed in the eastern USA and across Canada (See Figure 1) within a variety of Köppen–Geiger climate zones. The global Köppen–Geiger climate zones (Kottek et al., 2006) describe terrestrial climate in terms of average minimum winter temperatures and summer maxima, amount of precipitation and seasonality (rainfall pattern). In North America, *A. signatus* occurs in zones Cfa (warm temperate, fully humid hot summer), Cfb (warm temperate, fully humid, warm summer) and Dfb (snow, fully humid, warm summer); climate zones that also cover large portions of the EU where *Fragaria* and/or *Rubus* are grown.

Development and phenology studies suggest a temperature threshold for development of *A. signatus* to be around 8.3°C (Clarke & Howitt, 1975); thresholds below 10°C are typical for species in northern Europe.

Considering its distribution in North America, availability of hosts outdoors in Europe and its threshold temperature for development, *A. signatus* has the potential to establish in many parts of the EU.

As a pest of field grown strawberries and *Rubus*, *A. signatus* would not be expected to establish in glasshouses.

3.4.4. Spread

*Is the pest able to spread within the EU territory following establishment? (Yes or No) How?*

**Yes**, as a free living organism, adults can disperse naturally, e.g. by walking and, or flying.

Foord et al. (2017) reported that adult *A. signatus* rarely fly or walk more than 10 m while looking for food or places to lay eggs, hence spread is likely to be relatively slow. However, if accidentally transported with plants for planting, or as a hitchhiker, the pest could spread over greater distances in a short time.

3.5. Potential or observed impacts in the EU

*Would the pests’ introduction have an economic or environmental impact in the EU territory?*

**Yes**, the introduction of *A. signatus* could cause yield losses to susceptible *Fragaria* and / or *Rubus* crops.
3.5.1. Potential pest impacts

3.5.1.1. Direct impacts of the pest

Clarke & Howitt (1975) described *A. signatus* as one of the most important insect pests in Michigan strawberries between 1972 and 1975, after the withdrawal of organochlorine pesticides. *A. signatus* remained a major pest (Bostanian et al., 1999) and is still regarded as one of key insect pests of strawberries in north eastern North America (McPhie and Burrack, 2016, 2017). Yield loss is quite variable and depends on which buds are cut and which cultivars are fed upon (Kovach et al., 1999). Severe crop loss can be caused by high *A. signatus* infestations (Pritts et al., 1999). Early cultivars are more susceptible than late cultivars (Dorval, 1938; cited by Mailloux and Bostanian, 1993). Yield losses can have a ‘devastating effect’ on fruit growers because the loss occurs to the early season fruit which are the most valuable (Mailloux and Bostanian, 1993). Studies in the early 20th century cited in later literature quantify losses and note that reductions of 75% were not uncommon (Headlee, 1918; cited by Smith et al., 1997). Other quantified losses in strawberry are reported in Table 9.

Later literature reports strawberry cultivars compensating the loss of buds by increasing fruit weight from remaining buds and increasing the number of higher order buds matured (English-Loeb et al., 1999; McPhie and Burrack, 2016, 2017). However, whether compensating growth sufficiently recovers losses from impacts on early season fruit is doubtful. Harvest timing may be affected by *A. signatus* damage (McPhie and Burrack, 2017) and additional impact, e.g. on quality, cannot be discarded.

As insecticides are the only management tool available against *A. signatus* (McPhie and Burrack, 2016), and the insect activity period coincides with strawberry bloom, pesticide applications targeting the weevil would coincide with bees and other pollinators visiting *Fragaria* (as they have entomophilous pollination). As a consequence, negative impacts on pollination services could occur.

3.5.1.2. Indirect pest impacts (e.g. by bacteria or viruses transmitted by the pest)

Whilst a comprehensive literature review was not conducted, of the literature that was used for this categorisation, there was no suggestion that *A. signatus* transmits any plant pathogens.

3.6. Availability and limits of mitigation measures

<table>
<thead>
<tr>

Later literature reports strawberry cultivars compensating the loss of buds by increasing fruit weight from remaining buds and increasing the number of higher order buds matured (English-Loeb et al., 1999; McPhie and Burrack, 2016, 2017). However, whether compensating growth sufficiently recovers losses from impacts on early season fruit is doubtful. Harvest timing may be affected by *A. signatus* damage (McPhie and Burrack, 2017) and additional impact, e.g. on quality, cannot be discarded.

As insecticides are the only management tool available against *A. signatus* (McPhie and Burrack, 2016), and the insect activity period coincides with strawberry bloom, pesticide applications targeting the weevil would coincide with bees and other pollinators visiting *Fragaria* (as they have entomophilous pollination). As a consequence, negative impacts on pollination services could occur.

3.5.1.2. Indirect pest impacts (e.g. by bacteria or viruses transmitted by the pest)

Whilst a comprehensive literature review was not conducted, of the literature that was used for this categorisation, there was no suggestion that *A. signatus* transmits any plant pathogens.
3.6.1. Biological or technical factors affecting the feasibility and effectiveness of measures to prevent the entry, establishment and spread of the pest

Factors favouring the feasibility and effectiveness of measures to prevent entry, establishment and spread:

- Symptoms of the pest, i.e. cut buds, are visible during field inspections.
- Adults can be detected by visual inspection.
- Strawberry cuttings (stolons) traded as plants for planting without soil or growing media reduces the likelihood that overwintering stages will be present at pathway origin.
- Biological factors (one generation per year, sexual reproduction) hinder the likelihood of \textit{A. signatus} establishing; sluggish movement would hinder its rate of spread in the EU.

Factors disfavouring the feasibility and effectiveness of measures to prevent entry, establishment and spread:

- If whole plants for planting are harvested with a little soil, rather than taking aerial runners (stolons), overwintering adults sheltering under older plants could be transported along the pathway.
- Larvae develop and pupate inside buds where they are protected from contact insecticides and natural enemies.

3.6.2. Control methods

- Growers use chemical insecticides to control \textit{A. signatus} populations (Bostanian et al., 1999; McPhie and Burrack, 2016, 2017).
- Populations are suppressed by removing strawberry plants at the end of the season, to remove in field overwintering sites.
- Fields are kept weeds free and plant debris removed.
- Tolerant varieties are used in areas where the pest has a history of causing damage.
- Mixing staminate varieties (i.e. those with only male flowers) with pistillate varieties (only female flowers) in a ratio of 1:5 can lessen impacts (Metcalf and Metcalf, 1993).

3.7. Uncertainty

Although there are uncertainties, for example regarding the possible impacts that would result from \textit{A. signatus} establishing within the EU, the uncertainties are not sufficient as to cast doubt as to whether \textit{A. signatus} satisfies the criteria necessary for it to be regarded as a Union quarantine pest (Table 10).

4. Conclusions

\textit{A. signatus} meets the criteria assessed by EFSA for consideration as a potential Union quarantine pest.
Table 10: The Panel’s conclusions on the pest categorisation criteria defined in Regulation (EU) 2016/2031 on protective measures against pests of plants (the number of the relevant sections of the pest categorisation is shown in brackets in the first column)
