Pest categorisation of *Thecaphora solani*

Abstract

The Panel on Plant Health performed a pest categorisation of the fungus *Thecaphora solani*, the causal agent of smut of potato, for the EU. The identity of the pest is well established and reliable methods exist for its detection and identification. *T. solani* is present in Bolivia, Chile, Colombia, Ecuador, Mexico, Panama, Peru and Venezuela. The pathogen is not known to occur in the EU and is listed in Annex IAI of Directive 2000/29/EC, meaning its introduction into the EU is prohibited. The major host is *Solanum tuberosum* (potato), but various other tuber-forming *Solanum* species are also affected. The pest has also been reported on *Solanum lycopersicum* (tomato), and wild solanaceous plants are also affected. All the major hosts and pathways of entry are currently regulated. Host availability and climate matching suggest that *T. solani* could establish in parts of the EU and further spread by human-assisted means. The disease induces gall formation on potato tubers, stolons and underground stem parts, reducing yield and making tubers unmarketable. The pest introduction in the EU would potentially cause impacts to potato production. In the infested areas, the only available strategy to control the disease and prevent it from spreading is the application of quarantine and sanitation measures and the cultivation of resistant varieties. The main uncertainties concern the host range, the biology and epidemiology of the pest, and the potential of the pest to enter the EU through three unregulated minor pathways. *T. solani* meets all the criteria assessed by EFSA for consideration as potential Union quarantine pest. The criteria for considering *T. solani* as a potential Union regulated non-quarantine pest are not met, since the pest is not known to occur in the EU.

1. Introduction

1.1. Background and Terms of Reference as provided by the requestor

1.1.1. Background

Council Directive 2000/29/EC on protective measures against the introduction into the Community of organisms harmful to plants or plant products and against their spread within the Community establishes the present European Union plant health regime. The Directive lays down the phytosanitary provisions and the control checks to be carried out at the place of origin on plants and plant products destined for the Union or to be moved within the Union. In the Directive's 2000/29/EC annexes, the list of harmful organisms (pests) whose introduction into or spread within the Union is prohibited, is detailed together with specific requirements for import or internal movement.

Following the evaluation of the plant health regime, the new basic plant health law, Regulation (EU) 2016/2031 on protective measures against pests of plants, was adopted on 26 October 2016 and will apply from 14 December 2019 onwards, repealing Directive 2000/29/EC. In line with the principles of the above-mentioned legislation and the follow-up work of the secondary legislation for the listing of EU regulated pests, EFSA is requested to provide pest categorizations of the harmful organisms included in the annexes of Directive 2000/29/EC, in the cases where recent pest risk assessment/pest categorisation is not available.

1.1.2. Terms of reference

EFSA is requested, pursuant to Article 22(5.b) and Article 29(1) of Regulation (EC) No 178/2002, to provide scientific opinion in the field of plant health.

EFSA is requested to prepare and deliver a pest categorisation (step 1 analysis) for each of the regulated pests included in the appendices of the annex to this mandate. The methodology and template of pest categorisation have already been developed in past mandates for the organisms listed in Annex II Part A Section II of Directive 2000/29/EC. The same methodology and outcome is expected for this work as well.

The list of the harmful organisms included in the annex to this mandate comprises 133 harmful organisms or groups. A pest categorisation is expected for these 133 pests or groups and the delivery of the work would be stepwise at regular intervals through the year as detailed below. First priority covers the harmful organisms included in Appendix 1, comprising pests from Annex II Part A Section I and Annex II Part B of Directive 2000/29/EC. The delivery of all pest categorisations for the pests included in Appendix 1 is June 2018. The second priority is the pests included in Appendix 2, comprising the group of Cicadellidae (non-EU) known to be vector of Pierce's disease (caused by Xylella fastidiosa), the group of Tephritidae (non-EU), the group of potato viruses and virus-like organisms, the group of viruses and virus-like organisms of Cydonia Mill., Fragaria L., Malus Mill., Prunus L., Pyrus L., Ribes L., Rubus L. and Vitis L. and the group of Margarodes (non-EU species). The delivery of all pest categorisations for the pests included in Appendix 2 is end 2019. The pests included in Appendix 3 cover pests of Annex I part A section I and all pest categorisations should be delivered by end 2020.

For the above-mentioned groups, each covering a large number of pests, the pest categorisation will be performed for the group and not the individual harmful organisms listed under “such as” notation in the Annexes of the Directive 2000/29/EC. The criteria to be taken particularly under consideration for these cases, is the analysis of host pest combination, investigation of pathways, the damages occurring and the relevant impact.

Finally, as indicated in the text above, all references to ‘non-European’ should be avoided and replaced by ‘non-EU’ and refer to all territories with exception of the Union territories as defined in Article 1 point 3 of Regulation (EU) 2016/2031.

---

1.1.2.1. Terms of Reference: Appendix 1

List of harmful organisms for which pest categorisation is requested. The list below follows the annexes of Directive 2000/29/EC.

Annex IIA

(a) Insects, mites and nematodes, at all stages of their development

- Aleurococcus spp.
- Anthonomus bisignifer (Schenkling)
- Anthonomus signatus (Say)
- Aschistonyx eppoi Inouye
- Carposina niponensis Walsingham
- Enarmonia packardi (Zeller)
- Enarmonia prunivora Walsh
- Grapholita inopinata Heinrich
- Hishomonus physitis
- Leucaspis japonica Ckll.
- Listronotus bonariensis (Kuschel)

(b) Bacteria

- Citrus variegated chlorosis
- Erwinia stewartii (Smith) Dye

(c) Fungi

- Alternaria alternata (Fr.) Keissler (non-EU pathogenic isolates)
- Anisogramma anomala (Peck) E. Müller
- Apiosporina morbosa (Schwein.) v. Arx
- Ceratocystis virescens (Davidson) Moreau
- Cercoseptoria pini-densiflorae (Hori and Nambu) Deighton
- Cercospora angolensis Carv. and Mendes

(d) Virus and virus-like organisms

- Beet curly top virus (non-EU isolates)
- Black raspberry latent virus
- Blight and blight-like
- Cadang-Cadang viroid
- Citrus tristeza virus (non-EU isolates)
- Leprosis

Annex IIB

(a) Insect mites and nematodes, at all stages of their development

- Anthonomus grandis (Boh.)
- Cephalia lariaphila (Klug)
- Dendroctonus micans Kugelan
- Gilphinia hercyniae (Hartig)
- Gonipterus scutellatus Gyll.
- Ips amitinus Eichhof

- Numonia pyrivorella (Matsumura)
- Oligonychus perditus Pritchard and Baker
- Pissodes spp. (non-EU)
- Scirtothrips aurantii Faure
- Scirtothrips citri (Moultx)
- Scolytidae spp. (non-EU)
- Scrobipalopsis solanivora Povolny
- Tachypeterellus quadrigibbus Say
- Toxoptera citricida Kirk.
- Unaspis citri Comstock

- Xanthomonas campestris pv. oryzae (Ishiyama)
- Dye and pv. oryzicola (Fang, et al.) Dye

- Elsinoe spp. Bitanc. and Jenk. Mendes
- Fusarium oxysporum f. sp. albedinis (Kilian and Maire) Gordon
- Guignardia picricula (Nosa) Yamamoto
- Puccinia pittlerianna Hennings
- Stegophora ulmea (Schweinitz: Fries) Sydow & Sydow
- Venturia nashicola Tanaka and Yamamoto

- Little cherry pathogen (non- EU isolates)
- Naturally spreading psorosis
- Palm lethal yellowing mycoplasm
- Satsuma dwarf virus
- Tatter leaf virus
- Witches’ broom (MLO)
(b) Bacteria

*Curtobacterium flaccumfaciens pv. flaccumfaciens* (Hedges) Collins and Jones

(c) Fungi

*Glomerella gossypii* Edgerton  
*Hypoxylon mammatum* (Wahl.) J. Miller  
*Gremmeniella abietina* (Lag.) Morelet

1.1.2.2. Terms of Reference: Appendix 2

List of harmful organisms for which pest categorisation is requested per group. The list below follows the categorisation included in the annexes of Directive 2000/29/EC.

**Annex IAI**

(a) Insects, mites and nematodes, at all stages of their development

Group of Cicadellidae (non-EU) known to be vector of Pierce's disease (caused by *Xylella fastidiosa*), such as:

1) *Carneocephala fulgida* Nottingham  
2) *Draeculacephala minerva* Ball

Group of Tephritidae (non-EU) such as:

1) *Anastrepha fraterculus* (Wiedemann)  
2) *Anastrepha ludens* (Loew)  
3) *Anastrepha obliqua* Macquart  
4) *Anastrepha suspensa* (Loew)  
5) *Dacus ciliatus* Loew  
6) *Dacus curcurbitae* Coquillet  
7) *Dacus dorsalis* Hendel  
8) *Dacus tryoni* (Froggatt)  
9) *Dacus tsuneonis* Miyake  
10) *Dacus zonatus* Saund.  
11) *Epochra canadensis* (Loew)

(b) Viruses and virus-like organisms

Group of potato viruses and virus-like organisms such as:

1) Andean potato latent virus  
2) Andean potato mottle virus  
3) Arracacha virus B, oca strain  
4) Potato black ringspot virus  
5) Potato virus T  
6) non-EU isolates of potato viruses A, M, S, V, X and Y (including Yo, Yn and Yc) and Potato leafroll virus

Group of viruses and virus-like organisms of Cydonia Mill., Fragaria L., Malus Mill., Prunus L., Pyrus L., Ribes L., Rubus L. and Vitis L., such as:

1) Blueberry leaf mottle virus  
2) Cherry rasp leaf virus (American)  
3) Peach mosaic virus (American)  
4) Peach phony rickettsia  
5) Peach rosette mosaic virus  
6) Peach rosette mycoplasm  
7) Peach X-disease mycoplasm  
8) Peach yellows mycoplasm  
9) Plum line pattern virus (American)  
10) Raspberry leaf curl virus (American)  
11) Strawberry witches’ broom mycoplasm  
Annex IIA

(a) Insects, mites and nematodes, at all stages of their development

Group of Margarodes (non-EU species) such as:

1) Margarodes vitis (Phillipi) 3) Margarodes prieskaensis Jakubski
2) Margarodes vredendalensis de Klerk

1.1.2.3. Terms of Reference: Appendix 3

List of harmful organisms for which pest categorisation is requested. The list below follows the annexes of Directive 2000/29/EC.

Annex IIA

(a) Insects, mites and nematodes, at all stages of their development

Acleris spp. (non-EU)  Longidorus diadecturus  Eveleigh and Allen
Amauromyza maculosa (Malloch)  Monochamus spp. (non-EU)
Anomala orientalis Waterhouse  Myndus crudus Van Duzee
Arrhenodes minutus Drury  Nacobbus aberrans (Thorne) Thorne and Allen
Choristoneura spp. (non-EU)  Naupactus leucoloma Boheman
Conotrachelus nenuphar (Herbst)  Premnotrypes spp. (non-EU)
Dendrolimus sibiricus Tschelterverikov  Pseudopityophthorus minutissimus (Zimmermann)
Diabrotica barberi Smith and Lawrence  Pseudopityophthorus pruinicosus (Eichhoff)
Diabrotica undecimpunctata howardi Barber  Scaphoideus luteolus (Van Duzee)
Diabrotica undecimpunctata undecimpunctata Mannerheim  Spodoptera eridania (Cramer)
Diabrotica virgifera zeae Krysan & Smith  Spodoptera frugiperda (Smith)
Diaphorina citri Kuway  Thrips palmi Kamiy
Heliolucia zeae (Boddie)  Xiphinema americanum Cobb sensu lato (non-EU populations)
Hirschmanniella spp., other than  Xiphinema californicum Lamberti and Bleve-Zacheo
Hirschmanniella gracilis (de Man) Luc and Goodey
Liriomyza sativae Blanchard

(b) Fungi

Ceratocystis fagacearum (Bretz) Hunt  Mycosphaerella larici-leptolepis Ito et al.
Chrysomyxa arctostaphyli Dietel  Mycosphaerella populorum G. E. Thompson
Cronartium spp. (non-EU)  Phoma andina Turkensteen
Endocronartium spp. (non-EU)  Phyllosticta solitaria Ell. and Ev.
Guignardia laricina (Saw.) Yamamoto and Ito  Septoria lycopersici Speg. var. malagutii Ciccarone and Beerman
Gymnosporangium spp. (non-EU)  Thecaphora solani Barrus
Inonotus weirii (Murril) Kotlaba and Pouzar  Trechispora brinkmannii (Bresad.) Rogers
Melampsora farlowii (Arthur) Davis

(c) Viruses and virus-like organisms

Tobacco ringspot virus  Pepper mild tigré virus
Tomato ringspot virus  Squash leaf curl virus
Bean golden mosaic virus  Euphorbia mosaic virus
Cowpea mild mottle virus  Florida tomato virus
Lettuce infectious yellows virus
(d) Parasitic plants

Arceuthobium spp. (non-EU)

Annex I AII

(a) Insects, mites and nematodes, at all stages of their development

Meloidogyne fallax Karssen

Popillia japonica Newman

(b) Bacteria

Clavibacter michiganensis (Smith) Davis et al.

Ralstonia solanacearum (Smith) Yabuuchi et al.

(c) Fungi

Melampsora medusae Thümen

Synchytrium endobioticum (Schilbersky) Percival

Annex I B

(a) Insects, mites and nematodes, at all stages of their development

Leptinotarsa decemlineata Say

Liriomyza bryoniae (Kaltenbach)

(b) Viruses and virus-like organisms

Beet necrotic yellow vein virus

1.2. Interpretation of the Terms of Reference

Thecaphora solani is one of a number of pests listed in the Appendices to the Terms of Reference (ToR) to be subject to pest categorisation to determine whether it fulfils the criteria of a quarantine pest or those of a regulated non-quarantine pest (RNQP) for the area of the EU excluding Ceuta, Melilla and the outermost regions of Member States referred to in Article 355(1) of the Treaty on the Functioning of the European Union (TFEU), other than Madeira and the Azores.

2. Data and methodologies

2.1. Data

2.1.1. Literature search

A literature search on T. solani was conducted at the beginning of the categorisation in the ISI Web of Science bibliographic database, using the scientific name of the pest as search term. Relevant papers were reviewed and further references and information were obtained from experts, as well as from citations within the references and grey literature.

2.1.2. Database search

Pest information on host(s) and distribution was retrieved from the European and Mediterranean Plan Protection Organization (EPPO) Global Database (EPPO, online) and relevant publications.

Data about the import of commodity types that could potentially provide a pathway for the pest to enter the EU and about the area of hosts grown in the EU were obtained from EUROSTAT (Statistical Office of the European Communities).

The Europhyt database was consulted for pest-specific notifications on interceptions and outbreaks. Europhyt is a web-based network run by the Directorate General for Health and Food Safety (DG SANTE) of the European Commission, and is a subproject of PHYSAN (Phyto-Sanitary Controls) specifically concerned with plant health information. The Europhyt database manages notifications of interceptions of plants or plant products that do not comply with EU legislation, as well as notifications of plant pests detected in the territory of the Member States (MS) and the phytosanitary measures taken to eradicate or avoid their spread.
2.2. Methodologies

The Panel performed the pest categorisation for *T. solani*, following guiding principles and steps in the International Standard for Phytosanitary Measures No 11 (FAO, 2013) and No 21 (FAO, 2004).

This work was initiated following an evaluation of the EU plant health regime. Therefore, to facilitate the decision-making process, in the conclusions of the pest categorisation, the Panel addresses explicitly each criterion for a Union quarantine pest and for a Union RNQP in accordance with Regulation (EU) 2016/2031 on protective measures against pests of plants, and includes additional information required in accordance with the specific terms of reference received by the European Commission. In addition, for each conclusion, the Panel provides a short description of its associated uncertainty.

Table 1 presents the Regulation (EU) 2016/2031 pest categorisation criteria on which the Panel bases its conclusions. All relevant criteria have to be met for the pest to potentially qualify either as a quarantine pest or as a RNQP. If one of the criteria is not met, the pest will not qualify. A pest that does not qualify as a quarantine pest may still qualify as a RNQP that needs to be addressed in the opinion. For the pests regulated in the protected zones only, the scope of the categorisation is the territory of the protected zone; thus, the criteria refer to the protected zone instead of the EU territory.

It should be noted that the Panel’s conclusions are formulated respecting its remit and particularly with regard to the principle of separation between risk assessment and risk management (EFSA founding regulation (EU) No 178/2002); therefore, instead of determining whether the pest is likely to have an unacceptable impact, the Panel will present a summary of the observed pest impacts. Economic impacts are expressed in terms of yield and quality losses and not in monetary terms, whereas addressing social impacts is outside the remit of the Panel.

Table 1: Pest categorisation criteria under evaluation, as defined in Regulation (EU) 2016/2031 on protective measures against pests of plants (the number of the relevant sections of the pest categorisation is shown in brackets in the first column)

</table>
The Panel will not indicate in its conclusions of the pest categorisation whether to continue the risk assessment process, but following the agreed two-step approach, will continue only if requested by the risk managers. However, during the categorisation process, experts may identify key elements and knowledge gaps that could contribute significant uncertainty to a future assessment of risk. It would be useful to identify and highlight such gaps so that potential future requests can specifically target the major elements of uncertainty, perhaps suggesting specific scenarios to examine.

3. Pest categorisation

3.1. Identity and biology of the pest

3.1.1. Identity and taxonomy

*Is the identity of the pest established, or has it been shown to produce consistent symptoms and to be transmissible?*

**YES.** The identity of the pest is well-established.

*T. solani* is a soil-borne fungus of the family Glomosporiaceae. The Index Fungorum database ([www.indexfungorum.org](http://www.indexfungorum.org)) provides the following taxonomical identification:

**Current scientific name:** *Thecaphora solani* (Thirumulachar & M.J. O’Brien) Mordue, 1988

- Family – Glomosporiaceae
- Genus – *Thecaphora*
- Species – *solani*
Other reported synonyms (EPPO, online): *Angiosorus solani* Thirumulachar & M.J. O’Brien

Common name: smut of potato

Other common names (CABI online; EPPO, online): potato smut, thecaphora smut, thecaphora smut of potato

### 3.1.2. Biology of the pest

*T. solani* is a biotrophic plant pathogen and survives in soil for more than 7 years (O’Brien and Thirumulachar, 1972; Torres, 2002). There is limited information on the biology of the pest or the epidemiology of the disease (CABI, online). Except for roots, all underground plant parts are susceptible to infection by the pest (Torres, 2001). Infection takes place where there is high soil moisture (Torres, 2001). After penetration of the cortex, hyphae ramify profusely, growing toward the phloem and parenchyma. Upon reaching the cambium, the mycelium stimulates cell proliferation. This massive invasion by the fungus causes hypertrophy of the inner phloem and parenchyma tissues. Spores originate by compaction of the thick-walled hyphae at certain intervals. Uncertainty exists about the temperatures favouring infection and disease development because of lack of information in the available literature (Torres, 2001). The disease occurs in cool, mountainous areas, but it has also been found in warmer, coastal climates. It is also favoured by high humidity and saline soils, with its incidence increasing in the absence of crop rotation (Torres, 2001). Formation of galls is observed 45–60 days after planting (Torres, 2001).

Andrade et al. (2004) reported that isolates of the pest were grown *in vitro* on potato dextrose agar and malt yeast peptone agar at 18–20°C. However, *T. solani* teliospores have a very low germination capability. Only 27% of the isolates studied by Andrade et al. (2004) yielded cultures *in vitro*. Germination of teliospores did not involve the production of basidia and basidiospores or growth of a yeast-like anamorph. Mycelium grew slowly and produced both teliospores and chlamydospore-like structures. Zachmann and Baumann (1975) reported that teliospores did not germinate in water, soil extract, potato root extract or in the presence of potato growing roots, or on internal tissue of tubers of a susceptible variety. Based on the above and the observation that, in the coastal region of Peru, potato tubers were simultaneously infected with both the pest and nematodes of the genus *Meloidogyne* (root-knot nematodes), Zachmann and Baumann (1975) suggested a possible interaction between *T. solani* and nematodes. However, the disease has also been found at altitudes of 3,500 m in Peru, where the above-mentioned nematodes are not present (Torres, 2002).

### 3.1.3. Detection and identification of the pest

*Are detection and identification methods available for the pest?*

**Yes.** *Thecaphora solani* can be detected and identified based on host association, symptomatology, morphology and molecular methods.

*T. solani* can be detected and identified on a potato plant material based on symptomatology and morphology of its teliospores produced in galls.

*T. solani* can also be identified in culture by polymerase chain reaction (PCR) amplification of ribosomal DNA (LSU rDNA) from mycelium produced by germinating teliospores, and subsequent DNA sequencing (Andrade et al., 2004). Nevertheless, the low germination rate of teliospores makes the application of this method difficult. No official diagnostic protocols exist for the detection and identification of the pest.

**Symptoms**

The main symptom is galls developing below the soil line on stems, stolons and tubers of potato plants (Torres, 2001). Symptoms do not occur on aerial parts or roots of the infected plants (Torres, 2001). In general, the size and shape of galls depend mostly on the time of infection (Torres, 2001). The biggest galls are formed on underground stems, which are infected first. Their size varies from a few centimetres up to 10 cm or more (Torres et al., 1998), and may weigh over 300 g (Untiveros and de Icoechea, 1980). Galls on stolons may form anywhere along the length of the stolon and generally are smaller than those on stems. The galls formed on stems and stolons start as small lateral outgrowths but with time, they surround the organs to which they are attached.
On tubers, two types of symptoms are observed: (a) small galls, mostly at the apical end, which appear as secondary growths partially attached to the tubers and (b) slight protuberances on the surface of the tubers, which may appear in some varieties but not in others. In some cases, the latter symptoms look similar to those caused by the root-knot nematodes. After 2-3 months in storage, the protuberances become sunken and suberised (Torres, 2001). When these tubers sprout, new galls develop on the young sprouts or on the tuber surface near sprouts. The size of the galls formed on tubers varies from less than 1 mm to 4 cm or more in diameter (Acuña, 1981). Infected tubers are hard and misshapen (Chalkley, 2018). The whole or only part of the tuber may be infected. As symptoms appear mainly on underground parts of potato plants, the disease is often not noticed before harvest.

A very distinctive symptom is the presence of oval to irregular locular sori of variable sizes within the galls which contain a reddish-dark, granular-powdery mass of teliospores (Mordue, 1988; Vánky, 1988). Completely infected tubers later turn into dry, brown powdery masses of numerous spores (Chalkley, 2018).

Susceptibility of potato varieties to infection by *T. solani* varies (Bazan de Segura, 1960; Zachmann and Baumann, 1975). Several resistant accessions are available in the Potato Germplasm Collection of the International Potato Centre (CIP) (Torres and Martin, 1986; Torres, 2001).

On tomato, galls develop particularly at the junction of the stem and roots (Andrade, 2012; Chalkley, 2018).

Symptoms caused on potato tubers by *T. solani* may appear similar to those caused by powdery scab (*Spongospora subterranea* f. sp. *subterranea*), common scab (*Actinomyces scabies*), potato wart disease (*Synchytrium endobioticum*) or the damage caused by the root-knot nematode (*Meloidogyne incognita*). The smut fungus *Polysaccopsis hieronymi*, which affects wild *Solanum* species in South America, has sori similar to those of *T. solani*, however the spore balls of the former are black and consist of viable spores surrounded by sterile cells, whereas in the case of *T. solani*, the spores are not surrounded by sterile cells (O’Brien and Thirumalachar, 1972). Therefore, reliable detection and identification of the pest on potato plant material is only possible by laboratory examination.

**Morphology**

The sori are locular, 1–4 mm in diameter (EPPO, online). The sporiferous hyphae lining locules produces spore balls in the flesh of the galls. Immature locules are usually surrounded by brown corky tissue of potato. Mature spore balls comprise of 2–8 teliospores (rarely solitary), cinnamon to rust-brown, 15–50 × 12–40 μm in diameter (Zachmann and Baumann, 1975). Spores are pressed together but they can often be teased apart (EPPO, online). They are globose to angular, smooth on the contiguous side and densely verrucose on the free side, 7.5–20 × 8–18 μm.

**3.2. Pest distribution**

**3.2.1. Pest distribution outside the EU**

*T. solani* is indigenous to the Andean region of South America (EPPO, online) (Figure 1 and Table 2). At the end of the 1980s, the disease was widely distributed in South America (Bolivia, Chile, Colombia, Ecuador, Peru and Venezuela) and in the southern part of North America (Mexico) (Mordue, 1988; Torres, 2001; Andrade et al., 2004). It has also been reported from Panama (McGuire and Crandall, 1967). The pest has not been reported from any other part of the world.

3.4. Entry, establishment and spread in the EU

3.4.1. Host range

The major host of *T. solani* is cultivated potato (*Solanum tuberosum*) (EPPO, online), but various other tuber-forming species of *Solanum* are also affected, particularly *S. tuberosum* subsp. *andigenum* and *Solanum stoloniferum* (Mordue, 1988; EPPO, online). The pest has also been reported to affect...
Solanum lycopersicum (tomato) (Andrade, 2012), and solanaceous wild plants/weeds, such as Datura stramonium, a common weed in potato fields of the Andean region (Mordue, 1988; Torres, 2001; Andrade, 2012; EPPO, online).

S. tuberosum, which is the only major host of T. solani (EPPO, online), is regulated in the EU. Therefore, the Panel decided to focus this pest categorisation on S. tuberosum.

3.4.2. Entry

Is the pest able to enter into the EU territory? If yes, identify and list the pathways:

YES., however, all the pathways associated with host plants for planting and soil as commodity or substrate originating in infested third countries are regulated under the current EU legislation (Council Directive 2000/29/EC).

The PLH Panel identified the following pathways for the entry of T. solani from infested third countries into the EU territory, in the absence of the current EU legislation:

1) potato tubers intended for planting (seed tubers),
2) potato tubers intended for consumption or processing (ware potatoes), that may be planted (especially in small holdings and private gardens) or discarded (as whole potatoes or peels) or used for livestock feed,
3) host plant species of the genus Solanum intended for planting, other than S. tuberosum seed tubers,
4) soil adhering to potato tubers (seed and ware potatoes),
5) soil adhering to underground parts (tubers, bulbs, roots, etc.) of host and non-host plants for planting, other than potato seed tubers,
6) soil and growing media containing soil or organic substances not attached to or associated with plants (soil as commodity),
7) soil adhering to farm machinery and implements, footwear, vehicles, etc. (soil as contaminant)
8) waste (plant material and water) of potato processing industries used as fertiliser or irrigation, and
9) manure derived from livestock fed on infected potato tubers (whole tubers or peels) or having grazed in infested fields.

T. solani is not known to be seed-borne. The pest is unlikely to enter the EU territory by natural means (wind, water) because of the distance between the infested third countries and the risk assessment area, and the limited capacity of the pest for natural spread.

The following pathways of entry of T. solani into the EU territory are regulated by the current EU legislation (Table 3):

- potato tubers intended for planting (seed tubers) originating in third countries,
- tubers of S. tuberosum (ware potatoes) originating in infested third countries,
- stolon- or tuber-forming plants for planting of Solanum spp., or their hybrids, other than S. tuberosum seed tubers, originating in third countries,
- plants for planting of the family Solanaceae, other than S. tuberosum seed tubers and stolon- or tuber-forming Solanum species, originating in third countries, other than European non-EU-28 countries and Mediterranean countries,
- plants with roots, planted or intended for planting, grown in the open air in infested third countries,
- soil and growing media attached to or associated with plants originating in Turkey, Belarus, Georgia, Moldova, Russia, Ukraine and non-European countries, other than Algeria, Egypt, Israel, Libya, Morocco and Tunisia
- soil and growing media not attached to or associated with plants originating in Turkey, Belarus, Moldavia, Russia, Ukraine and third countries not belonging to continental Europe other than Egypt, Israel, Libya, Morocco and Tunisia.

Based on the above, all the pathways associated with host plants for planting, and soil as commodity or substrate, originating in infested third countries are regulated (Council Directive 2000/29/EC).

Three of the potential pathways of entry are currently not regulated:

- soil adhering to agricultural machinery and implements, footwear, vehicles, etc.,
• manure of livestock fed on infected potato tubers or having grazed in infested fields in third countries,
• waste of potato processing industries originating in infested third countries and used as fertiliser.

The Panel considers these three potential pathways as uncertain because of the distance between the infested countries and the risk assessment area, and due to the absence of import data in the Eurostat database (accessed on 2/5/2018). These pathways are therefore not considered as major pathways and not further addressed in the following sections.

According to Eurostat, during the period 2011–2015, an average of around 360 000 tonnes of potato tubers was imported from third countries yearly; the amount of potato tubers originating in infested countries is negligible (Table 5).

Table 5: Volume (in tonnes) of potato tubers imported during the period 2011–2015 into the EU from third countries (Source: Eurostat, extracted on 3/5/2018).

There is no record of interception of *T. solani* in the Europhyt database (online; search performed on 22 May 2018).

### 3.4.3. Establishment

**Is the pest able to become established in the EU territory?**

**YES.** The biotic (host availability) and abiotic (climate suitability) factors occurring in the risk assessment area are favourable for the establishment of *T. solani*.

#### 3.4.3.1. EU distribution of main host plants

Potatoes are widely grown in the EU territory (Table 6).

Table 6: Area (in 1,000 ha) cultivated with *Solanum tuberosum* in the 28 EU Member States between 2011 and 2015 (Source: Eurostat, extracted on 3/5/2018).

Thecaphora solani: Pest categorisation
3.4.3.2. Climatic conditions affecting establishment

*T. solani* is known to occur in the Andean region of South America, Mexico and Panama. These areas are characterised by different Köppen–Geiger climate types (Peel et al., 2007) (Figure 2). The prevalent climate type is the tropical (mainly: Af, rainforest; Am, monsoon; Aw, savannah). Arid (mainly: BWh, desert, hot; BWk, desert, cold; BSk, steppe, cold) and, to a lesser extent, temperate (mainly: Cfb, without dry season, warm summer; Csb, dry and warm summer; Cwb, dry winter, warm summer; Cwc, dry winter, cold summer) climate types are also present.

In the EU, tropical climate types are not present. However, Cfb, Csb and BSk are present in central Europe, the UK, Ireland and in the Iberian Peninsula. Therefore, the climate is suitable for the establishment of *T. solani* in parts of the EU.

![Köppen–Geiger climate type world map](image)

**Figure 2**: Köppen–Geiger climate type world map, from Peel et al. (2007)
3.4.4. Spread

3.4.4.1. Vectors and their distribution in the EU (if applicable)

*Is the pest able to spread within the EU territory following establishment? Yes*

*How?* Mainly by human-assisted means

*RNQPs: Is spread mainly via specific plants for planting, rather than via natural spread or via movement of plant products or other objects?*

**NO.** Spread of the pest is mainly via the movement of (i) infected potato seed tubers, and (ii) soil adhering to underground parts of host and non-host plants for planting, other than potato seed tubers

Spread by natural means. T. solani has limited capacity for spread by natural means (EPPO, online). Torres (2001) reported that teliospores can be dispersed within a field or between neighbouring fields by irrigation water.

Spread by human-assisted means. The pest can spread over long distances through the trade/movement of infected potato tubers (Abbott, 1932) and infested soil adhering to potato tubers or below ground parts of host and non-host plants (e.g. roots, bulbs, stolons, etc.) or any other object (e.g. farm machinery, implements and footwear used in infested fields, vehicles visiting infested areas, etc.). Since 1984, T. solani has been intercepted by the USDA over 125 times in tubers of S. tuberosum and S. stoloniferum, almost all from Mexico (CABI, online).

T. solani could also be spread via hoofs of animals moving from one field to another as well as through manure from livestock fed on infected potato tubers or having grazed in infested fields (Torres, 2001; Andrade, 2012). The pest could potentially be spread via waste (e.g. discarded potatoes, soil, water) from potato processing industries used as fertiliser, land fill or irrigation water (Efremenko and Yakovleva, 1981; Langerfeld, 1984; Steinmöller et al., 2004). Potato processing is an important industrial sector in many EU MSs, including Germany, where 3 million tonnes of waste are produced of which the major part is used as fertiliser (Steinmöller et al., 2012).

3.5. Impacts

*Would the pests' introduction have an economic or environmental impact on the EU territory?*

**YES.** The introduction of the pest would potentially cause direct and indirect impacts to potato production in the EU territory.

*RNQPs: Does the presence of the pest on plants for planting have an economic impact, as regards the intended use of those plants for planting?*

**YES.** The presence of the pest on potato seed tubers has an economic impact as regards their intended use for planting.

Potatoes rank fourth on the list of world food crops, after maize, rice and wheat (FAOSTAT, online). The total world potato production was estimated at 381.7 million tonnes in 2014. The EU ranks third in fresh potato production after China and India (FAOSTAT, online). In 2015, the EU produced 53.2 million tonnes of potatoes, with Germany, France and the Netherlands as the largest producers (Table 7). The value of EU potato production, including seed potatoes, at basic prices was EUR 10 billion, representing 2.5% of the total EU agricultural output and 4.7% of the crop output at EU level (de Cicco and Jeanty, 2017). Most potatoes are traded in the internal EU market. The EU is a net potato exporter, but potatoes are imported into its territory in winter and spring from southern and eastern non-EU Mediterranean countries (de Cicco and Jeanty, 2017), and rarely from infested areas in Latin and Central America (Table 5).
With regard to the impact of *T. solani* in infested areas, Torres and Henfling (1984) indicated that the disease can reduce yields of susceptible potato varieties by up to 85%. In Peru, production losses between 50% and 89% were reported during 1958 and 1959 in susceptible potato varieties (Bazan de Segura, 1960). Later, Zachmann and Baumann (1975) reported incidences between 11% and 42% of diseased tubers in susceptible potato varieties in Peru. In Chile, Andrade (2012) indicated yield losses ranging from 20% to 75%, depending on the region and inoculum sources (i.e. infested soil, infected tubers). Likewise, in Chile, Torres et al. (1998) reported disease incidence of 80% on harvested tubers of susceptible varieties. In Colombia, incidences of 21–46% on harvested tubers of susceptible varieties were reported by Sotelo and García (2001).

The introduction of the pest in the EU territory would potentially cause direct and indirect impacts to potato production.

</tbody>
</table>

<table>
<thead>
<tr>
<th>RNQPs: Are there measures available to prevent pest presence on plants for planting such that the risk becomes mitigated?</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>YES.</strong> The presence of <em>T. solani</em> on host and non-host plants for planting could be prevented by sourcing them in pest-free areas or places of production</td>
</tr>
</tbody>
</table>

### 3.6.1. Identification of additional measures

Phytosanitary measures are currently applied to potato seed or ware tubers and non-host plants or plant parts (bulbs, roots, tubers, etc.) for planting, including the soil attached to them: sourcing from pest-free areas or pest-free places of production, inspection and lab testing at the place of origin and at the EU entry point, quarantine and sanitation measures (See Section 3.3). There are no additional unregulated major hosts or pathways of entry.

Section 3.4.2 lists three minor pathways of entry currently unregulated and uncertain. Should the pest be introduced in the risk assessment area, these three pathways should be assessed as potential means of spread and possible mitigation measures be evaluated (EFSA PLH Panel, 2018).

#### 3.6.1.1. Biological or technical factors limiting the feasibility and effectiveness of measures to prevent the entry, establishment and spread of the pest

The following factors can limit the feasibility and effectiveness of measures to prevent the entry, establishment and spread of *T. solani*:

- **Inspection:** (i) the similarity of symptoms caused by *T. solani* on underground parts of potato plants with those caused by other potato pathogens (e.g. *Spongospora subterranea* f. sp. *subterranea*, *Synchytrium endobioticum*, *Actinomyces scabies*, etc.) or pests (nematodes) makes visual inspection for the detection of the pathogen difficult and unreliable (see Section 3.1.3), (ii) inconspicuous galls present on potato tubers may go undetected during visual inspection, (iii) teliospores carried as contaminants on the surface of potato tubers, underground parts of non-host plants and other objects (e.g. farm machinery and implements, footwear, etc.) cannot be detected by visual inspection, and (iv) the long incubation period (45–60 days) and the development of symptoms on below ground parts of potato plants (tubers, stolons) reduces the effectiveness of visual inspection during the growing season for the early detection of the pest.

- **Laboratory testing:** the low germination capability of the teliospores and the lack of official diagnostic protocols make detection and identification of the pest on plant material and in soil difficult (see Section 3.1.3).

- **Chemical control:** the lack of effective chemical substances to be used as soil disinfectants or on the crop reduces the effectiveness of eradication of the pest.

#### 3.6.1.2. Biological or technical factors limiting the ability to prevent the presence of the pest on plants for planting

Lack of effective plant protection products that can be applied to the crop or soil to prevent the presence of the pest on potato seed tubers (Sotelo and García, 2001; Andrade, 2012).

### 3.7. Uncertainty

1) **Host range.** It is not known whether wild species of the genus *Solanum* present in the EU territory are hosts of the pest.

2) **Entry.** Uncertainty exists on whether the pest could enter the EU territory on (i) soil adhering to agricultural machinery and implements, footwear, vehicles, etc., (ii) manure of livestock fed on infected potato tubers or having grazed in infested fields in third countries, and (iii) waste of potato processing industries originating in infested third countries and intended to be used as fertiliser because of the distance between the infested countries and the risk assessment area, and due to the absence of import data in the Eurostat database.
4. Conclusions

*T. solani* meets all the criteria assessed by EFSA for consideration as potential Union quarantine pest (Table 8). The criteria for considering *T. solani* as a potential Union RNQP are not met since the pest is not known to be present in the EU.

**Table 8:** The Panel’s conclusions on the pest categorisation criteria defined in Regulation (EU) 2016/2031 on protective measures against pests of plants (the number of the relevant sections of the pest categorisation is shown in brackets in the first column)

<table>
<thead>

<tbody>
<tr>
<td>Identity of the pest (Section 3.1)</td>
<td>The identity of the pest (<em>Thecaphora solani</em>) is clearly defined and there are reliable methods for its detection and identification</td>
<td>The identity of the pest (<em>Thecaphora solani</em>) is clearly defined and there are reliable methods for its detection and identification</td>
<td>None</td>
</tr>
<tr>
<td>Absence/presence of the pest in the EU territory (Section 3.2)</td>
<td>The pest is not known to be present in the EU territory</td>
<td>The pest is not known to be present in the EU territory</td>
<td>None</td>
</tr>
<tr>
<td>Regulatory status (Section 3.3)</td>
<td>The pest is currently officially regulated in the EU as a quarantine pest (Council Directive 2000/29/EC)</td>
<td>The pest is currently officially regulated in the EU as a quarantine pest (Council Directive 2000/29/EC). There are no grounds to consider its status could be revoked</td>
<td>None</td>
</tr>
<tr>
<td>Pest potential for entry, establishment and spread in the EU territory (Section 3.4)</td>
<td>All the major hosts and pathways of entry are currently regulated (Council Directive 2000/29/EC)</td>
<td>The pest can spread in the EU territory through the movement of potato tubers (seed tubers, ware potatoes) and soil as commodity or contaminant [attached to potato tubers, or below ground parts of non-host plants, or other objects (e.g. farm machinery and implements, footwear, etc.)]. Therefore, potato seed tubers are not the only major means of spread</td>
<td>1) The host status of wild <em>Solanum</em> plant species present in the EU territory is not known (Uncertainty 1) 2) Uncertainty exists on whether the pest could enter the EU territory on (i) soil adhering to agricultural machinery and implements, footwear, vehicles, etc., (ii) manure of livestock fed on infected potato tubers or having grazed in infested fields in third countries, and (iii) waste of potato processing industries originating in infested third countries and intended to be used as fertiliser (Uncertainty 2)</td>
</tr>
<tr>
<td>Potential consequences in the EU territory (Section 3.5)</td>
<td>The introduction of the pest in the EU territory would potentially cause direct and indirect impacts to potato production.</td>
<td>The presence of the pest on potato seed tubers has an economic impact, as regards the intended use of that plant material</td>
<td>None</td>
</tr>

<th>Criterion of pest categorisation</th>
<th>Panel's conclusions against criterion in Regulation (EU) 2016/2031 regarding Union quarantine pest</th>
<th>Panel's conclusions against criterion in Regulation (EU) 2016/2031 regarding Union regulated non-quarantine pest</th>
<th>Key uncertainties</th>
</tr>
</thead>
<tbody>
<tr>
<td>Available measures (Section 3.6)</td>
<td>There are measures available to prevent the entry into, establishment and spread of the pest within the EU. These include pest-free areas or places of production, inspection and lab testing of imported potato tubers and soil adhering to them or below ground parts of non-host plants, cultivation of resistant potato varieties, waste management, cleaning and disinfecting farm machinery and implements, etc. The currently applied phytosanitary measures (Council Directive 2000/29/EC) are effective in preventing the entry but not the establishment or spread of the pest in the EU</td>
<td>The presence of the pest on host and non-host plants for planting could be prevented by sourcing them in pest-free areas or places of production</td>
<td>None</td>
</tr>
<tr>
<td>Conclusion on pest categorisation (Section 4)</td>
<td>Thecaphora solani meets all the criteria assessed by EFSA for consideration as potential Union quarantine pest</td>
<td>The criteria for considering T. solani as a potential Union regulated non-quarantine pest are not met since the pest is not known to be present in the EU and plants for planting is not its only major means of spread</td>
<td>None</td>
</tr>
<tr>
<td>Aspects of assessment to focus on/ scenarios to address in future if appropriate</td>
<td>None</td>
<td></td>
